24   **Abstract**

25   An offshore operations thermodynamic-dynamic prediction model of sea ice break-up and drift is presented for

26   central coastal Labrador in Atlantic Canada, and demonstrated for portions of the 2015 spring break-up of the land-

27   fast ice. The model validation is performed using the data from ice tracking buoys deployed on the land-fast ice,

28   which began drifting after break-up of the land-fast ice. The model uses a one-dimensional thermodynamic

29   parameterization for ice melt and growth, includes snow accumulation and melt, and melt-pond and lead growth and

30   contraction. The dynamic model uses a Smoothed Particle Hydrodynamics (SPH) parameterization for ice motion

31   and changes in ice thickness and concentration. The dynamic forcing parameters include wind and ocean current

32   drag, Coriolis deflection, internal ice stresses, and gravitational forcing due to sea surface gradients. A coastal

33   repulsion force is employed to prevent ice particles from crossing the coastal boundaries. The model is sensitive to

34   the prescribed initial snow depth on the sea ice. In the present work, analysis of results is focused on the offshore

35   regions of Makkovik and Nain, Labrador. The melt of the coastal land-fast ice in these regions can be adequately

36   simulated by the thermodynamic model alone. The model predicts the timing of the local land-fast ice break-up to

37   within 4.6 hours to six days, and can simulate observed ice buoy drift speeds to within 1.5 meters per second.

38   **1 Introduction**

39   Sea ice forecast models are an important tool for offshore industries operating in ice-prone environments, such as

40   those involved in hydrocarbon exploration and development or marine transport. Accurate pack ice model forecasts

41   allow for operations to be planned for maximum safety, efficiency, and minimum downtime as operators make the

42   best possible preparations for the anticipated ice conditions, and can develop an advance understanding of how those

43   conditions and associated hazards are likely to evolve during operations. While small-scale models are useful for

44   generating drift forecasts for single or several ice floes over spatial scales of up to tens of km, regional and basin-

45   scale models provide forecasts of ice conditions on scales of tens to hundreds of km, and permit operators to develop

46   a picture of changes in ice conditions over such a broad area in which vessels and drilling platforms may travel.

47   Such forecast models are useful for generating ice forecasts on timescales of days to months.

48   In this paper, a model is presented to simulate the melt and break-up of the land-fast ice along the central Labrador

49   coast during the spring break-up season, as well as the regional ice dynamics in the further offshore marginal ice

50   zone (MIZ). The model is designed to be an operational planning and ice forecast tool for the offshore oil and gas

51   industry, as well as the marine transport industry. It is designed to accept gridded metocean input parameters from

52   numerical weather prediction and ocean models. The model simulations presented here are run for selected periods

53   during April-May 2015, and are compared to in-situ observations of ice drift as recorded by tracking buoys deployed

54   on ice floes, and to reanalysis data on ice thickness, concentration, and velocity as provided by the Operational

55   Mercator global Ocean analysis and forecast system. The models runs are forced with atmospheric and precipitation

56   reanalysis data from the North American Regional Reanalysis (NARR), the European Center for Medium Range

57   Weather Forecasting (ECMWF), and with ocean model output from the Operational Mercator global Ocean analysis

58   and forecast system.

59   The results presented here focus particularly on the regions offshore Makkovik and Nain, Labrador, as these

60   locations have been identified as economically important for vessel transit. Makkovik has been identified as a

61   potential landing site for a pipeline from oil and gas fields offshore Labrador, and Nain is located near the port of

62   Edward's Cove which serves the Voisey's Bay nickel mine (Vale, 2015). In this paper, two locations offshore

63   Makkovik and Nain are selected to demonstrate the thermodynamic model simulation of the melt and break-up of

64   the land-fast ice during April 1 – May 31, 2015. Results from the thermodynamic model are also presented for the

65   central coastal Labrador region from Makkovik to Nain. Subsequently, the coupled thermodynamic-dynamic model

66   is demonstrated for the Makkovik-Nain region for May 1-7, 2015, which coincides with the break-up of the land-fast

67   ice offshore Nain.

68   **1.1 Ice tracking buoy deployments**

69   On April 9, 2015, six Iridium satellite-tracked buoys were deployed toward the outer edge of the land-fast ice

70   offshore Labrador (see Figure 1). The buoys were dropped out of a Twin Otter fixed-wing airplane, and were

71   deployed in two triangular arrays offshore Makkovik and Nain. These buoy deployments served to collect data on

72   the precise timing of the land-fast ice break-up at these locations during the 2015 melt season, and the subsequent

73   drift patterns of the broken floes. Table 1 summarizes the offshore deployment areas for the six buoys and the time

74   periods over which they drifted on ice following the break-up of the land-fast ice on which they were deployed. The

75   on-ice drift periods were determined from analysis of the internal temperatures transmitted by the buoys, as the on-

76   ice periods were characterized by distinctly larger diurnal temperature fluctuations in response to air temperatures,

77   compared with more homogeneous temperature records once the buoys fell into open water. The open water drift of

78   the buoys is not considered in this paper.

79   Buoys 1, 4, and 6 were deployed offshore Nain, and buoys 2, 3, and 5 were dropped offshore Makkovik. The first

80   drift motion recorded by the buoys took place on April 23 offshore Makkovik, and on May 1 offshore Nain. Buoy 5

81   failed on May 28 on the land-fast ice offshore Makkovik and never recorded any movement (Table 1).

**April-June 2015 Ice Tracking Buoy Trajectories**
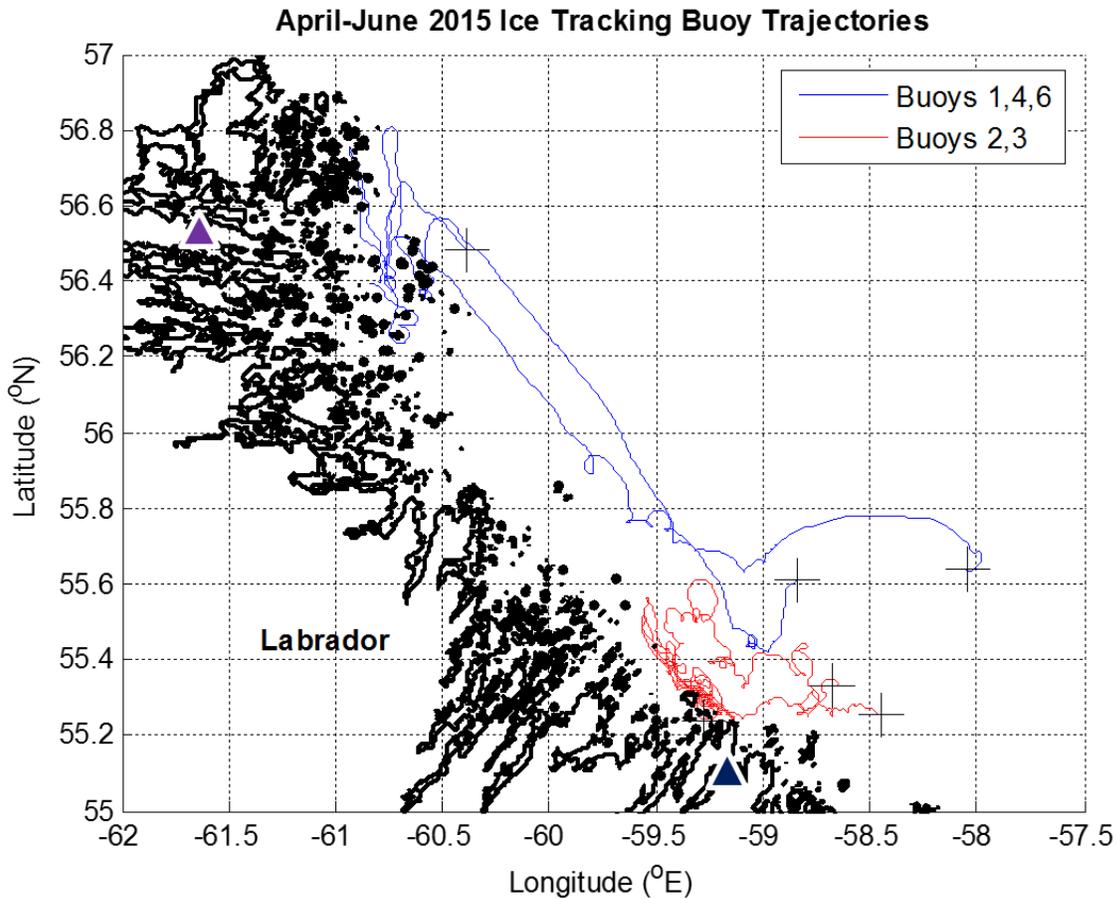

82

83   **Figure 1.** Trajectories of six ice tracking buoys offshore Labrador during April 23 – June 12, 2015. The dark blue
84   and purple white-outlined triangles mark the locations of Makkovik and Nain, respectively. The black plus (+)
85   symbols mark the ends of the buoys' on-ice drift trajectories.

86   **Table 1.** Deployment areas and time periods over which the six ice buoys drifted on ice following the break-up of
87   the land-fast ice.

| Buoy	Deployment Area	Ice Drift Period
1	Nain	May 1-18
2	Makkovik	April 23 – June 12
3	Makkovik	April 23 - June 8
4	Nain	May 2-11
5	Makkovik	N/A
6	Nain	May 6-19

88   **1.2 Regional environment**

89   Coastal Labrador is dominated by the Labrador Current, which has a mean surface speed of 0.25-0.5 m s⁻¹ (Lazier

90   and Wright, 1993) toward the south and SSE, parallel to the coast (Figure 2).

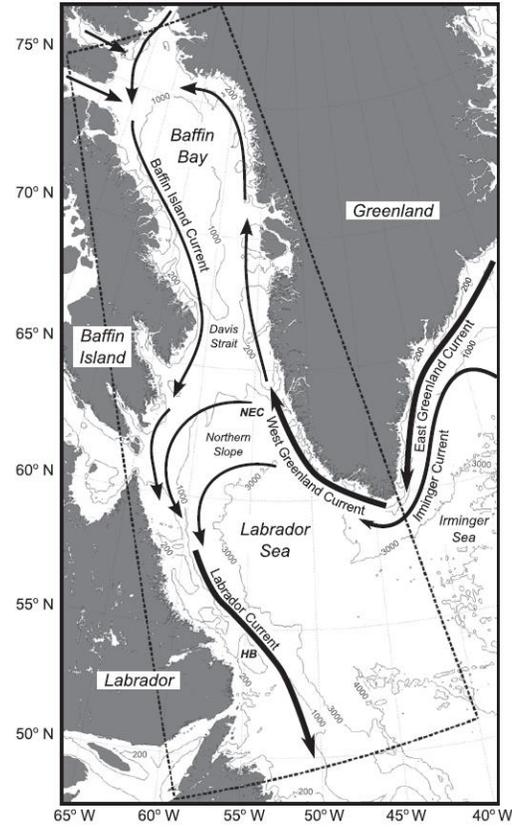

91

92   **Figure 2.** Mean surface currents offshore Labrador flow parallel to the coast toward the south and SSE at speeds of

93   0.25-0.5 m s⁻¹ (image reproduced from Fenty and Heimbach, 2013).

94   Freeze-up along the Labrador coast typically begins in December, with land-fast ice forming from the northern edge

95   of Labrador to just south of Lake Melville (Canadian Coast Guard, 2013). By April 1ˢᵗ, a large region of 9+/10ths

96   mainly first-year (FY) ice has formed further offshore from the land-fast ice and drifts southward with the Labrador

97   Current, being replenished by more northerly-sourced ice from Baffin Bay (Figure 3). The boundary between the

98   regions of 9+/10ths pack ice and open water is typically sharp and along the edge of the Labrador Shelf (see Figure

99   5) near the western edge of the Labrador Current (Yao et al., 2000b), with only a thin band of ice 1-8/10ths in

100   concentration along the boundary (Figure 3).
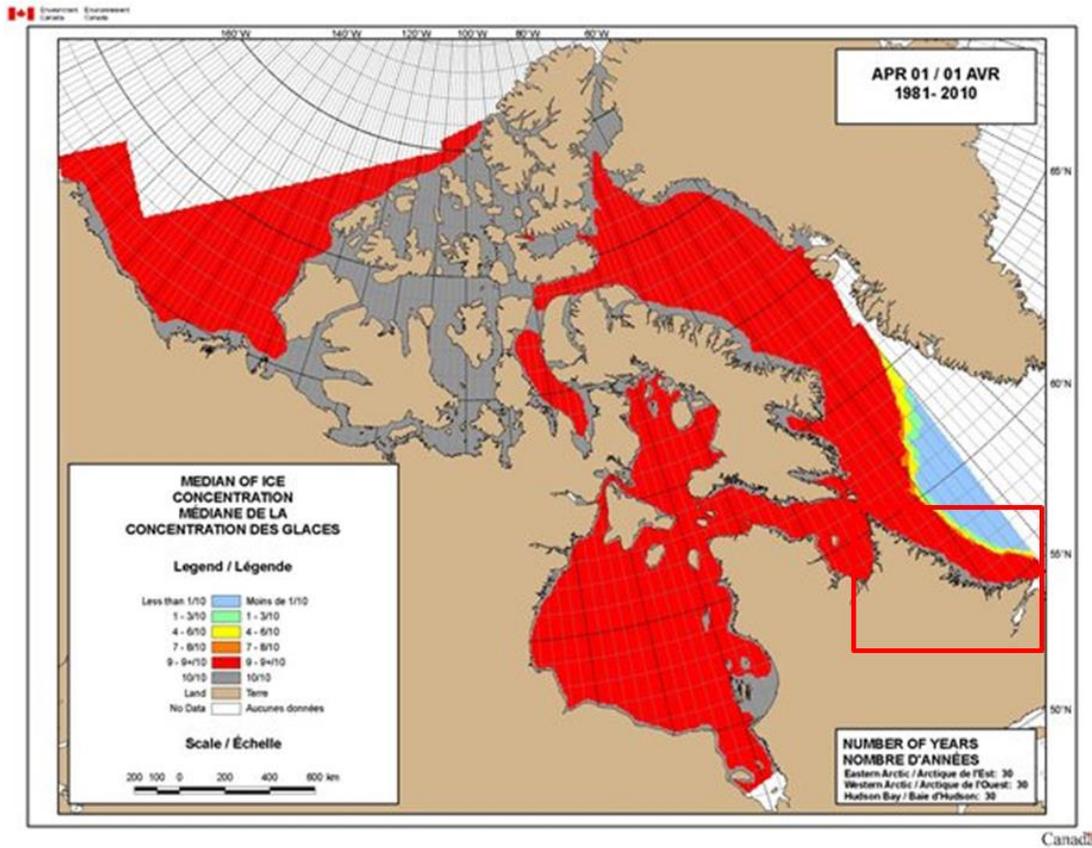

Figure 3. Maximum spring ice cover offshore Labrador (red-boxed region) typically includes a band of 10/10ths land-fast ice (gray region), and a more extensive zone of dynamic pack ice 9+/10ths in concentration (red region) further offshore (Canadian Coast Guard, 2013).

The onset of break-up of the high-concentration ice along the coast of Labrador typically occurs in mid-June for most of the region, with break-up commencing in early July for the most northerly areas (Figure 4).
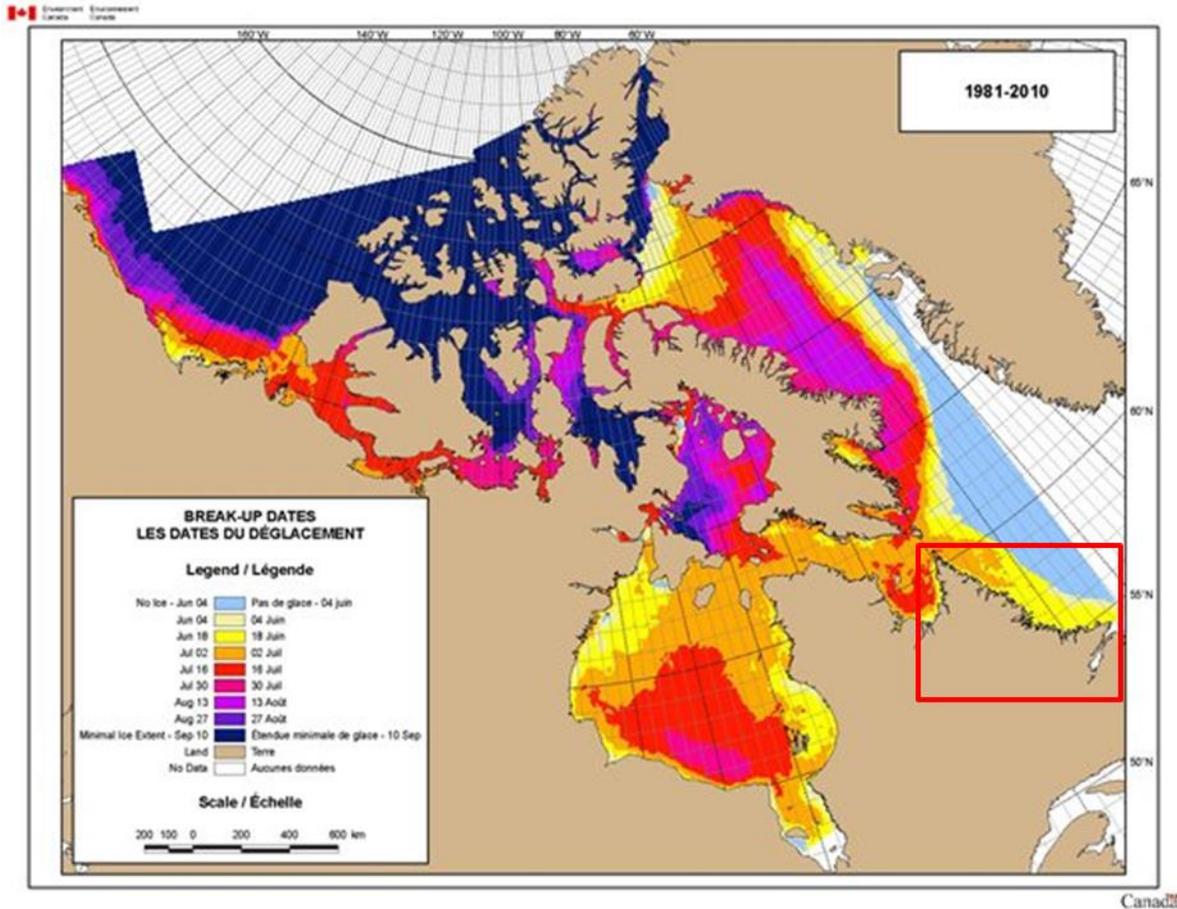

Figure 4. The onset of pack ice break-up in the offshore Labrador region (red-boxed region) typically occurs in mid-June to early July (Canadian Coast Guard, 2013).

The water depth offshore Labrador extends to approximately 500 m along the Labrador Shelf, with a few pockets as deep as about 1000 m (Figure 5). Further offshore, the depth rapidly increases to greater than 2000 m. At its maximum seasonal extent in March-April, sea ice typically extends to the shelf break front (Yao et al., 2000b) along the 500 m depth contour.
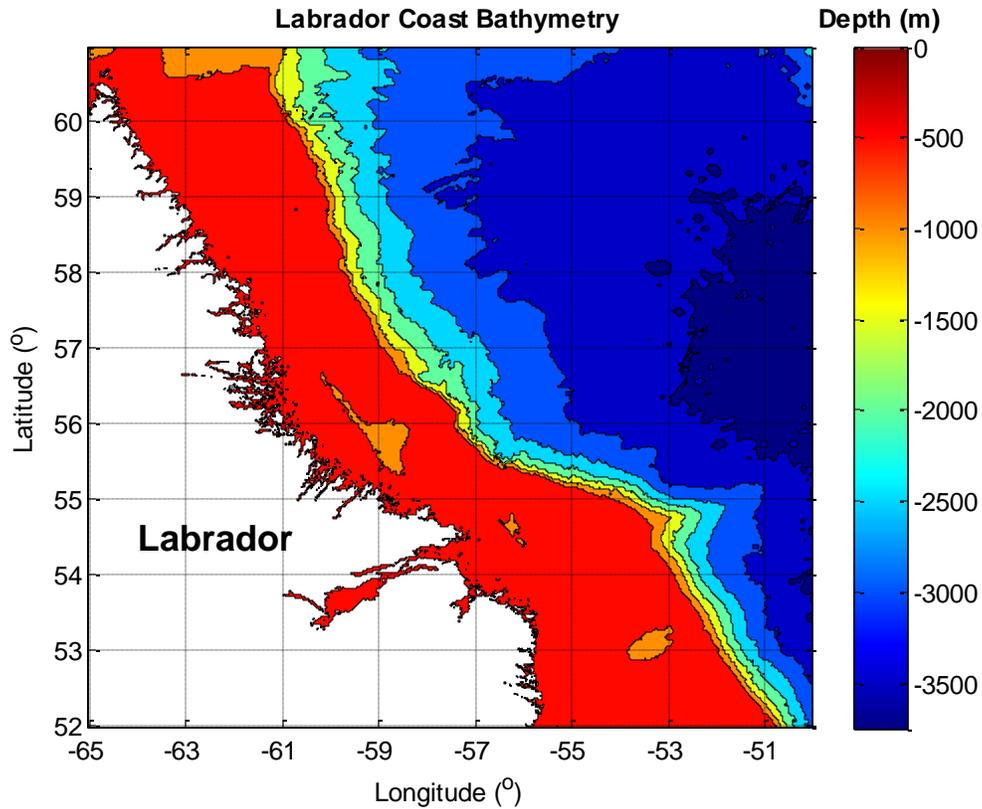

Figure 5. The bathymetry offshore Labrador (General Bathymetric Chart of the Oceans, GEBCO, 2008, 30-second data).

2 Ice Environmental Modeling

2.1 Previous modeling studies

Existing modelling studies for the offshore Labrador ice environment tend to focus on seasonal to inter-annual sea ice variability and its interaction with oceanic mixing and convection. Few studies have presented efforts to develop operational ice forecast models for the region.

A study by Peng, 1989, for example, applies a coupled ice-ocean model to simulate ice growth and transport in the Labrador Sea over a single winter season.

Prinsenberg and Yao, 1999 presents a climatological study of the seasonal evolution of sea ice cover offshore eastern Canada for 1991-1992 using a three-dimensional coupled ice-ocean model. The study additionally presents model simulations of ice cover under a scenario of a doubling of atmospheric carbon dioxide concentration by using as input the expected atmospheric conditions under such a scenario.

128 A paper by Yao, 2000 focuses on the assimilation of satellite-derived sea surface temperature (SST) data into a

129 coupled ice-ocean model for the Labrador Sea, with the primary objective of improving the modelled location of the

130 ice edge. The SST data assimilation, however, did not improve model performance in this regard.

131 A study by Yao et al., 2000a focuses on verification of a coupled ice-ocean model for the Newfoundland shelf

132 during February-April 1997, with the region of interest (ROI) stretching from offshore central-northern

133 Newfoundland to southern Labrador. The model output was compared in particular to observed ice edge location,

134 southern ice extent, and ice thickness as derived from Canadian Ice Service (CIS) charts, and to ice drift velocities as

135 measured by satellite-tracked ice buoys.

136 Yao et al., 2000b presents results of a modelling study of the seasonal variation of sea ice in the Labrador Sea using

137 an ice model coupled to the Princeton ocean model. In this paper, the Princeton ocean model is forced by monthly

138 climatological atmospheric data.

139 A paper by Sayed et al., 2002 presents the operational ice dynamics model developed by CIS for ice forecasting in

140 regional environments. The model uses a Lagrangian Particle-In-Cell (PIC) approach to model ice advection. In the

141 paper, a seasonal simulation of the model is presented, with the ice model coupled to the Princeton ocean model.

142 The model output is compared with the measured trajectory of a single ice tracking beacon offshore Labrador during

143 January-April 1999, and with the January-May 1999 evolution of the total ice area and mean thickness over a large

144 area encompassing the east coast of Canada.

145 A study by Fenty and Heimbach, 2013 explores the relationship between sea ice and oceanic variability in the

146 Labrador Sea and Baffin Bay. It analyzes the response of the annual sea ice cover variability to ocean currents and

147 water mass mixing and convection in the region.

148 A paper by Cooke et al., 2014 presents a study of inter-annual sea ice variability in the western Labrador Sea using a

149 coupled sea ice-ocean model. The paper focuses on the relationships between sea ice concentration and the

150 underlying water column properties in terms of temperature, salinity, and convection. Cooke et al., 2014 use the

151 Nucleus for European Modelling of the Ocean (NEMO) model and couple it to the Louvain Sea Ice Model 2 (LIM2)

152 multi-layered sea ice model. Atmospheric forcing is provided by the National Center for Environmental

153 Prediction/National Center for Atmospheric Research (NCEP/NCAR) six-hourly reanalysis data from 1948-2005.

154 **2.2 Thermodynamic model description**

155 The model presented in this paper was developed in the programming language of MATLAB. The thermodynamic

156 model is largely based on the one-dimensional model presented in Ebert and Curry, 1993 (hereafter referred to as

157 EC93), which is in turn based on the model presented in Maykut and Untersteiner, 1971. The thermodynamic model

158 can be run as a standalone model, or can be coupled to the dynamic ice model. The thermodynamic model accounts

159 for heat fluxes from the surface ocean through the ice slab, heat exchanges with the surface air or snow layer if

160 present, snow layer accumulation, melt, and heat exchange with the ice and atmosphere, incoming shortwave (solar)

161 radiation, total cloud cover and its effects on atmospheric albedo and down-welling longwave radiation, and lead

162 and melt pond growth and contraction. The thermodynamic model-only runs are initialized with ice particles on a

163   grid with 0.45° spacing (approximately 50 km). Ice particles are dropped from the model grid once they have
164   completely melted away.

2.2.1 Ice and snow thermal properties and heat conduction

166   In the thermodynamic model, the sea ice vertical temperature profile and thickness are governed by the one-
167   dimensional heat equation as per EC93,

168    $$(\rho c)_i \left(\frac{\partial T_i}{\partial t}\right) = k_i \left(\frac{\partial^2 T_i}{\partial z^2}\right) = \frac{\partial F_c}{\partial z}, \tag{1}$$

169   where $(\rho c)_i$ is the volumetric heat capacity of ice, T_i is ice temperature (K), t is time (seconds), k_i is the thermal
170   conductivity of ice, F_c is the upward conductive flux (W m^{-2}), and z is the depth level in the ice slab (m) with $z = 0$
171   defined at the ice surface. As the heat capacity and thermal conductivity of ice are affected by its temperature and
172   salinity, the volumetric heat capacity of the sea ice (J m^{-3} K^{-1}) is defined as (*e.g.*, EC93),

173    $$(\rho c)_i = (\rho c)_{i,f} + \frac{\gamma S_i}{(T_i - 273)^2}, \tag{2}$$

174   where $(\rho c)_{i,f}$ is the volumetric heat capacity of pure ice (1.883x10^6 J m^{-3} K^{-1}) and γ is a constant (1.715×10^7 J K m^{-3}
175   ppt^{-1}), and S_i is the ice salinity (ppt). The ice thermal conductivity (W m^{-1} K^{-1}) is defined as (*e.g.*, EC93),

176    $$k_i = k_{i,f} + \frac{B S_i}{T_i - 273}, \tag{3}$$

177   where $k_{i,f}$ is the thermal conductivity of pure ice (2.034 W m^{-1} K^{-1}), and B is a constant (0.1172 W m^{-1} ppt^{-1}). As per
178   EC93, T_i is constrained to values 272.9K or less in order to avoid a singularity at 273K in Eqs. (2) and (3). The ice
179   salinity (ppt) is approximated by the equation from Timco and Johnston, 2002 for cold FY ice as a function of
180   thickness, *e.g.*,

181    $$S_i = 13.4 - 17.4 h_i \qquad\qquad \text{for } h_i \le 0.34\text{m,}$$

182    $$S_i = 8.0 - 1.62 h_i \qquad\qquad \text{for } h_i > 0.34\text{m,} \tag{4}$$

183   where h_i is ice thickness (m).

184   The ice temperature profile is initialized with a linear trend between the boundary conditions set at the ice base and
185   surface. The ice basal temperature is fixed at the melting point of seawater, and the ice surface temperature is
186   calculated as a function of the surface (2m) air temperature. The ice temperature is calculated at four evenly-spaced
187   points in the vertical slab, including the boundaries at the ice-water and ice-snow or ice-air (when no snow is
188   present) interfaces.

189   The snow-free ice surface temperature is calculated as a function of the surface air temperature according to the
190   function (*e.g.*, Timco and Frederking, 1990),

191    $$T_{i,s} = T_a \qquad\qquad \text{for -2} \ge T_a \ge \text{-10,}$$

192    $$T_{i,s} = 0.6 T_a - 4 \qquad\qquad \text{for } T_a < \text{-10,}$$

193     $T_{i,s} = -2.0$ for $T_a > -2$,   (5)

194   where $T_{i,s}$ is the ice surface temperature (°C), and T_a is the 2 m air temperature (°C). When the air temperature is

195   higher than -2°C, the ice surface temperature is assumed to be at the approximate freezing point of saline FY sea ice,

196   -2°C.

197   The basal ice temperature is calculated as the freezing temperature of seawater as a function of sea surface salinity

198   (*e.g.*, Fofonoff and Millard Jr., 1983),

199     $T_{o,f} = -5.33x10^{-7}S^3 - 9.37x10^{-6}S^2 - 0.0592S$,   (6)

200   where $T_{o,f}$ is the freezing temperature of seawater (°C), and S is the sea surface salinity (ppt).

201   When a snow layer is present on the sea ice, the snow vertical temperature profile is governed by a similar one-

202   dimensional heat equation as that used for sea ice (*e.g.*, EC93),

203     $(\rho c)_s \left(\frac{\partial T_s}{\partial t}\right) = k_s \left(\frac{\partial^2 T_s}{\partial z^2}\right) = \frac{\partial F_c}{\partial z}$,   (7)

204   where $(\rho c)_s$ is the volumetric heat capacity of snow, T_s is the snow temperature (K), k_s is the thermal conductivity

205   of snow, and z is again defined with $z = 0$ at the snow surface. The snow temperature is calculated at three evenly-

206   spaced points in the vertical slab, including the boundaries at the snow-ice and snow-air interfaces. The volumetric

207   heat capacity of snow is given by (*e.g.*, EC93),

208     $(\rho c)_s = \rho_s(92.88 + 7.364T_s)$,   (8)

209   where ρ_s is the density of the snow layer (kg m^{-3}) on the sea ice. The value of ρ_s is 330 kg m^{-3} if the surface air

210   temperature is less than 0°C, and is 450 kg m^{-3} if the surface air temperature is 0°C or greater (EC93). Compaction

211   of the snow layer due to fresh snowfall and time is neglected in the present model. The snow thermal conductivity is

212   given by (*e.g.*, EC93),

213     $k_s = 2.845 \times 10^{-6}\rho_s^2 + 2.7 \times 10^{-4} \times 2^{\frac{T_s - 233}{5}}$.   (9)

214   The temperature at the snow-ice interface is computed from Eq. (7) and is set to the ice surface temperature. The

215   temperature at the snow-air interface is initialized in K by (*e.g.*, Tonboe et al., 2011),

216     $T_{s,top} = 1.14T_a - 37.94$ for $T_a < 273.15$,

217     $T_{s,top} = 273.15$ for $T_a \geq 273.15$.   (10)

218   Snow temperatures are constrained to 0°C and below. The effect of sea water flooding on the snow surface is

219   neglected in this model. As with the vertical ice temperature profiles, at the start of each model run, the vertical

220   snow temperatures are initialized with linear vertical profiles. From the second time-step forward, the temperature at

221   the snow or snow-free ice surface is solved using the net surface heat flux (see Eq. 49 in section 2.2.7).

222   **2.2.2 Solar radiation**

223   The incoming solar (shortwave) radiation (W m^{-2}) at the top of the atmosphere is given by (*e.g.*, FAO, 2015),

224    $$F_{SW} = \frac{12 S_o d_r \left((\omega_2 - \omega_1) \sin(\phi) \sin(\lambda) + \cos(\phi) \cos(\lambda)(\sin(\omega_2) - \sin(\omega_1)) \right)}{\pi}, \tag{11}$$

225   where S_o is the solar constant (1365.5 W m^{-2}), d_r is the inverse relative Earth-Sun distance (radians), ω_1 and ω_2 are

226   the solar time angles (radians) immediately before and after a given time-step, respectively, ϕ is the latitude

227   (radians), and λ is the solar declination (radians). The inverse relative Earth-Sun distance is defined by (*e.g.*, FAO,

228   2015),

229    $$d_r = 1 + 0.033 \cos\left(\frac{2\pi J}{365}\right), \tag{12}$$

230   where J is the Julian date. The solar declination is defined by (*e.g.*, FAO, 2015),

231    $$\lambda = 0.409 \sin\left(\frac{2\pi J}{365} - 1.39\right). \tag{13}$$

232   The solar time angles are given by (*e.g.*, FAO, 2015),

233    $$\omega_1 = \omega - \frac{\pi dt}{24},$$

234    $$\omega_2 = \omega + \frac{\pi dt}{24}, \tag{14}$$

235   where ω is the solar time angle (radians) at the midpoint of the period over which the incoming solar radiation is

236   calculated, and dt is the length of the calculation period (hours). The solar time angle at the midpoint of the period is

237   defined by (*e.g.*, FAO, 2015),

238    $$\omega = \frac{\pi \left((t + 0.06667(L_z - L_m) + S_c) - 12 \right)}{12}, \tag{15}$$

239   where t is the standard clock time at the hour midpoint (*e.g.*, $t = 13.5$ if the calculation time is between 13:00 and

240   14:00 hours), L_z is the longitude of the center of the local time zone (60°W for the Atlantic Standard Time or AST

241   zone) in degrees west of Greenwich, L_m is the longitude of the calculation site in degrees west of Greenwich, and S_c

242   is the seasonal correction for solar time (hours). The solar time seasonal correction is given by (*e.g.*, FAO, 2015),

243    $$S_c = 0.1645 \sin(2b) - 0.1255 \cos(b) - 0.025 \sin(b), \tag{16}$$

244   where b is defined as $\frac{2\pi(J-81)}{364}$ (FAO, 2015).

245   Finally, the sunset hour angle ω_s (radians) is used to determine whether or not the sun is below the horizon at a

246   given time. The sunset hour angle is defined as (*e.g.*, FAO, 2015),

247    $$\omega_s = \mathrm{acos}(-\tan(\phi)\tan(\lambda)). \tag{17}$$

248   The sun is below the horizon when $\omega < -\omega_s$ or $\omega > \omega_s$ and $F_{SW} = 0$. Note that times used to calculate F_{SW} are

249   local times for AST, which is UTC-3:00 during April-May.

250   The flux of solar radiation (W m^{-2}) which penetrates the snow-free ice surface as a function of depth in the ice, z

251   (m), is governed by Beer's Law (*e.g.*, EC93),

252    $F_{i0}(z) = I_0(1 - \alpha_i)F_{SW}e^{-\kappa_i(z)},$ (18)

253   where I_0 is the fraction of solar radiation which penetrates the atmosphere, α_i is the ice albedo, and κ_i is the bulk

254   shortwave extinction coefficient for sea ice (1.5 m^{-1}). The fraction of solar radiation penetrating the atmosphere is

255   defined by (*e.g.*, EC93),

256    $I_0 = 0.18(1 - T_{cc}) + 0.35T_{cc},$ (19)

257   where T_{cc} is the total fractional cloud cover. If there is snow on the sea ice, then Eq. (18) becomes,

258    $F_{i0}(z) = (1 - \alpha_i)F_{i0,s}e^{-\kappa_i(z)},$ (20)

259   where $F_{i0,s}$ is the fraction of solar radiation which penetrates the snow layer. The fraction of solar radiation

260   penetrating the snow layer is given by,

261    $F_{i0,s} = I_0(1 - \alpha_s)F_{SW}e^{-\kappa_s(z)},$ (21)

262   where α_s is the snow albedo, κ_s is the bulk shortwave extinction coefficient for snow (0.42 m^{-1} as per Davis, 1996),

263   and z (m) is the depth in the snow layer. The fractions of penetrating solar radiation determined from Eqs. (18) and

264   (21) are used to update the ice and snow temperature profiles as computed from Eqs. (1) and (7), respectively. In

265   Eqs. (1) and (7), the quantity F_c is replaced with F_{i0} and $F_{i0,s}$, respectively.

2.2.3 Meltwater ponds

267   The model presented here allows for the growth and contraction of meltwater ponds on the surface of the sea ice in

268   terms of the depth and fractional area coverage of the ponds. The rate of meltwater pond depth change (m s^{-1}) is

269   defined by (*e.g.*, EC93 and Holland et al., 2012),

270    $\frac{\partial h_p}{\partial t} = \left(\left(1 - A_{pond}\right)\left(\frac{\partial h_i}{\partial t}\right)_0 + \frac{A_{pond}F_p}{L_{fi}} + RF + \frac{SF\rho_s}{\rho_w}\right)(1 - r),$ (22)

271   where h_p is pond depth (m), A_{pond} is pond fractional area, $\left(\frac{\partial h_i}{\partial t}\right)_0$ is the rate of ice melt at the top surface of the sea

272   ice (m s^{-1}), F_p is the solar radiation flux (W m^{-2}) which is absorbed by both the pond water and the underlying sea

273   ice, L_{fi} is the latent heat of fusion of sea ice (3.014×10^8 J m^{-3}), RF and SF are rainfall and snowfall, respectively (m

274   s^{-1}), ρ_w is the density of melt-pond water (1000 kg m^{-3}), and r is the fraction of surface meltwater and rainfall which

275   runs off the ice surface while the rest remains in the ponds. The quantity r is defined as $0.85 - 0.7A_{ice}$ (Holland et

276   al., 2012), where A_{ice} is the fractional ice area concentration of a given model particle. As per EC93, once the melt-

277   pond depth on a given model particle is greater than zero, the melt-pond fractional area is initialized at 0.10.

278   The flux of solar radiation absorbed by the pond water and sea ice is defined by (*e.g.*, EC93),

279    $F_p = F_{SW}\left(a_p + a_p\alpha_i t_p + t_p(1 - \alpha_i)(1 - I_0)\right)(1 - \alpha_p),$ (23)

280   where a_p is the pond absorption coefficient $(1 - t_p^{0.89})$, t_p is the pond transmissivity $(0.36 - 0.17 \log_{10}(h_p))$, and

281   α_p is the pond albedo. As per EC93, the maximum allowed melt-pond depth is set to 0.8 m. Any melt-ponds which

282   grow to a depth greater than the ice thickness (when the ice thickness is less than 0.8 m) are subsequently treated as

283   leads in the ice pack (see subsection 2.2.4).

284   One melt ponds have begun to form, the melt-pond fractional area is computed iteratively using the scheme of

285   Holland et al., 2012 which allows for growth and contraction of the ponds based on the ice surface temperature. The

286   evolution of the melt-pond fractional area in terms of growth and contraction is defined respectively as follows,

287     $A_{pond(i+1)} = A_{pond(i)} + \dfrac{(1-r)\left(\left(\frac{\partial h_i}{\partial t}\right)_0 \left(\frac{\rho_i}{\rho_w}\right) + RF\right)}{h_p} dt$ for $T_{i,s} > -2°C$,

288     $A_{pond(i+1)} = A_{pond(i)} e^{\frac{0.01(T_{i,s}+2)}{2}}$ for $T_{i,s} \leq -2°C$,   (24)

289   where i is the model time-step index, and dt is the model time-step (seconds). As per EC93, the melt-pond

290   fractional area is restricted to a maximum value of 0.25. Melt-ponds are not permitted to form until all of the snow

291   has melted from a model particle.

292   **2.2.4 Lead development and ocean heat fluxes**

293   The present model uses the parameterizations of EC93 to simulate the ocean-air and ocean-ice heat exchanges and

294   the development of leads in the ice pack. The net heat flux (W m^{-2}) at the lead surface is defined by (*e.g.*, EC93),

295     $F_{lead} = \epsilon_w F_{LW} - \epsilon_w \sigma T_w^4 + (1 - \alpha_w)(1 - i_w)F_{SW} - F_{sens,w} - F_{lat,w},$ (25)

296   where ϵ_w is the emissivity of water (0.97), F_{LW} is the incoming (downward) infrared heat flux from the atmosphere

297   (W m^{-2}), σ is the Stefan-Boltzmann constant (5.67×10^{-8} W m^{-2} K^{-4}), T_w is the surface ocean temperature (K), α_w is

298   the surface ocean albedo, i_w is the fraction of solar radiation transmitted through the surface water layer equivalent

299   in depth to the ice thickness and not absorbed, and $F_{sens,w}$ and $F_{lat,w}$ are the sensible and latent heat fluxes from the

300   ocean surface layer, respectively (W m^{-2}). The parameter i_w is defined as follows (*e.g.*, EC93),

301     $i_w = 1 - \dfrac{(a_1 + a_2 \ln(h_i))}{1 - \alpha_w},$ (26)

302   where $a_1 = 0.5676$ and $a_2 = 0.1046$ under clear-sky conditions and $a_1 = 0.3938$ and $a_2 = 0.1208$ under cloudy-

303   sky conditions. In the present model, conditions are considered to be clear-sky if the total cloud area fraction is less

304   than 0.35.

305   The growth of the fractional lead area is defined by (*e.g.*, EC93),

306     $\dfrac{\partial A_{lead}}{\partial t} = \dfrac{A_{lead} F_{lead}}{L_{fi} h_i + L_{fs} h_s},$ (27)

307   where L_{fs} is the latent heat of fusion of snow (1.097×10^8 J m^{-3}), and h_s is the thickness of the snow layer on the ice

308   (m).

309 The expression for the solar radiation flux (Wm^{-2}) absorbed beneath the ice is represented as the sum of the solar

310 flux through the leads and the solar radiation transmitted through snow-free ice and is given as follows (*e.g.*, EC93),

311 $$F_{wi} = A_{lead}(1 - \alpha_w)i_w F_{SW} + (1 - A_{lead})(1 - \alpha_i)I_0 e^{-\kappa_i h_i} F_{SW}. \tag{28}$$

312 The water temperature immediately beneath the ice, T_{wi}, is governed by (*e.g.*, EC93),

313 $$\frac{\partial T_{wi}}{\partial t} = \frac{F_{wi} - (1 - A_{lead})F_b}{\left(d_w - \left(\frac{\rho_i}{\rho_w}\right)h_i\right)(\rho c)_w}, \tag{29}$$

314 where F_b is the heat flux at the base of the ice (W m^{-2}), d_w is the ocean mixed layer depth (m), and $(\rho c)_w$ is the

315 volumetric heat capacity of water (4.19×10^6 J m^{-3} K^{-1}). In deeper water, the ocean mixed layer depth is assumed to

316 be 30 m (EC93), and is assumed to be the bathymetric water depth in shallower water less than 30 m deep (see

317 Figure 5). The model is initialized with $T_{wi} = T_{o,f}$ as per Eq. (6). The heat flux at the base of the ice is given by

318 (*e.g.*, EC93),

319 $$F_b = (\rho c)_w C_{Tb}\left(T_{wi} - T_{o,f}\right), \tag{30}$$

320 where C_{Tb} is the bulk transfer coefficient. As per EC93, C_{Tb} is defined as,

321 $$C_{Tb} = 1.26 \times 10^{-4} h_i^{-0.5} \qquad\qquad\qquad \text{for } h_i < 3 \text{ m,}$$

322 $$C_{Tb} = 7.27 \times 10^{-5} \qquad\qquad\qquad\qquad \text{for } h_i \geq 3 \text{ m.} \tag{31}$$

323 **2.2.5 Atmospheric properties and heat fluxes**

324 The ocean and ice atmospheric heat fluxes in the present model are defined by the bulk aerodynamic formulae for

325 sensible, latent, and longwave radiative heat transfer as per EC93. The sensible heat flux over ice (W m^{-2}) is defined

326 as (*e.g.*, EC93),

327 $$F_{sens,i} = \rho_a c_{pa} C_{Ti} U_a (T_{i,s} - T_a), \tag{32}$$

328 where ρ_a is the air density (kg m^{-3}) at 2 m, c_{pa} is the specific heat of air at constant pressure (J kg^{-1} K^{-1}), C_{Ti} is the

329 bulk heat and moisture transfer coefficient over ice, and U_a is the wind speed at 2 m (m s^{-1}). The air density is

330 computed according to the ideal gas law as (*e.g.*, Tsonis, 2002),

331 $$\rho_a = \frac{P_s}{RT_a}, \tag{33}$$

332 where P_s is the surface or sea level atmospheric pressure (Pa), R is the gas constant for air (J kg^{-1} K^{-1}), and the 2 m

333 air temperature T_a is in K. The gas constant for air depends on the air specific humidity as follows (*e.g.*, Tsonis,

334 2002),

335 $$R = R_d(1 + 0.61q_a), \tag{34}$$

336 where R_d is the gas constant for dry air (278.058 J kg^{-1} K^{-1}), and q_a is the specific humidity of the air at 2 m. The air

337 specific humidity is defined by (*e.g.*, Tsonis, 2002),

338 $\quad q_a = \dfrac{\frac{0.622 e_w}{P_s - e_w}}{1 + \left(\frac{0.622 e_w}{P_s - e_w}\right)},$ (35)

339 where e_w is the vapor pressure in the air (Pa) at 2 m. The vapor pressure is equivalent to $(RH)(e_{sw})$, where RH is

340 the relative humidity at 2 m, and e_{sw} is the saturation vapor pressure (Pa) at 2 m. The saturation vapor pressure is

341 given by (*e.g.*, Tsonis, 2002),

342 $\quad e_{sw} = 611 e^{19.83 - \frac{5417}{T_a}},$ (36)

343 where T_a is in K. The specific heat of air at constant pressure is defined as $\frac{7}{2}R$ (Tsonis, 2002). The bulk heat and

344 moisture transfer coefficient over ice is defined as (*e.g.*, EC93),

345 $\quad C_{Ti} = C_{T0i} \left(1 - \dfrac{2 b_a Ri_{ice}}{1 + c|Ri_{ice}|^{0.5}}\right)$ $\qquad$ for $Ri_{ice} < 0,$

346 $\quad C_{Ti} = C_{T0i}(1 + b_a Ri_{ice})^{-2}$ $\qquad$ for $Ri_{ice} \geq 0,$ (37)

347 where C_{T0i} is a heat and moisture transfer coefficient for a neutral surface layer over ice (1.3×10^{-3}), b_a is a

348 parameter for atmospheric turbulence equal to 20, Ri_{ice} is the bulk Richardson number over ice, and c has a value of

349 $(1961 b_a C_{T0i})$ for an ice roughness length of 1.6×10^{-4} m. The Richardson number is defined as (*e.g.*, EC93),

350 $\quad Ri_{ice} = \dfrac{g(T_a - T_{i,s})\Delta z}{T_a U_a^2},$ (38)

351 where g is the earth gravitational acceleration (9.81 m s^{-2}), and Δz is the height of the wind speed and air

352 temperature data (2 m).

353 The latent heat flux over sea ice (W m^{-2}) is given as (*e.g.*, EC93),

354 $\quad F_{lat,i} = \rho_a L_v C_{Ti} U_a (q_{sat(Ti,s)} - q_a),$ (39)

355 where L_v is the latent heat of vaporization (2.501×10^6 J m^{-3}), and $q_{sat(Ti,s)}$ is the saturation specific humidity over

356 ice. This quantity is equal to (*e.g.*, WHOI, 2010),

357 $\quad q_{sat(Ti,s)} = \dfrac{0.622 e_{sat,i}}{P_s - 0.378 e_{sat,i}},$ (40)

358 where $e_{sat,i}$ is the saturation vapor pressure directly over the ice (Pa), which is equivalent to (*e.g.*, WHOI, 2010),

359 $\quad e_{sat,i} = 10^{\frac{0.7859 + 0.03477 T_{i,s}}{1 + 0.00412 T_{i,s}} + 0.00422 T_{i,s} + 2}.$ (41)

360 As per EC93, the formulas for the sensible and latent heat fluxes over leads and open water (W m^{-2}), $F_{sens,w}$ and

361 $F_{lat,w}$, respectively, are similar to those for ice (Eqs. 32 and 39). For the sensible heat flux over water, the quantity

362 $T_{i,s}$ in Eq. (32) is replaced with T_w to represent the surface water temperature. In Eq. (32), the bulk heat and moisture

363 transfer coefficient over water, C_{Tw}, is determined using Equation 37 with $C_{T0} = 1.0 \times 10^{-3}$ over water, and the

364 bulk Richardson number over water, Ri_{water}, is calculated by replacing T_a with T_w in Eq. (38). The latent heat flux

365 over water is computed by replacing C_{Ti} with C_{Tw} in Equation 39, and $q_{sat(Ti,s)}$ with $q_{sat(Tw)}$, the saturation specific

366   humidity over water. The quantity is computed from Equation 40, however saturation vapor pressure directly over

367   water, $e_{sat,w}$ (Pa), is determined by replacing $T_{i,s}$ with T_w in Equation 41, and multiplying Eq. (41) by 0.98.

368   The downward longwave (infrared) radiative flux from the atmosphere to the ocean and ice (Wm^{-2}) is defined by

369   (*e.g.*, Konig-Langlo and Augstein, 1994),

370    $$F_{LW} = (0.765 + 0.22 T_{cc}^3)\sigma T_a^4, \tag{42}$$

371   where the quantity $(0.765 + 0.22 T_{cc}^3)$ represents the atmospheric emissivity as a function of the total fractional

372   cloud cover area.

373   **2.2.6 Albedo**

374   The surface albedo parameterization follows the scheme used in EC93, in which there are five surface types

375   considered: dry snow, melting snow, bare ice, meltwater ponds, and open water. The albedo scheme additionally

376   considers the spectral variation in the incoming shortwave radiation in four ranges of wavelength, as well as the

377   albedo dependence on solar zenith angle. The solar zenith angle is given by,

378    $$\theta_0 = \text{acos}(\mu_0), \tag{43}$$

379   where the quantity μ_0 is defined as,

380    $$\mu_0 = \sin(\phi)\sin(\delta) + \cos(\phi)\cos(\delta)\cos(\theta_h). \tag{44}$$

381   In Eq. (44), δ is defined as (*e.g.*, NOAA, 2015),

382    $$\delta = 0.006918 - 0.399912\cos(d) + 0.070257\sin(d) - 0.006758\cos(2d) + 0.000907\sin(2d) -$$

383    $$0.002697\cos(3d) + 0.00148\sin(3d), \tag{45}$$

384   where the quantity d is defined by $d = \frac{2\pi(J-1)}{365.2422}$ and is given in radians. In Eq. (44), θ_h is the hour angle, and is

385   defined as $\theta_h = 15(T_{hr} - M) - L_m$, in which T_{hr} is the hour of the day (*e.g.*, 13 for 13:00) and M is defined by

386   (*e.g.*, NCEP, 2015),

387    $$M = 12 + 0.12357\sin(d) - 0.004289\cos(d) + 0.153809\sin(2d) + 0.060783\cos(2d). \tag{46}$$

388   The relative weights assigned to each wavelength band of the solar spectrum, as well as the fractions of diffuse

389   versus direct radiation, are summarized in Table 2 as a function of month (*e.g.*, EC93).

390   **Table 2.** Summary of solar spectrum relative weights as a function of wavelength band and month, as well as

391   fractions of diffuse versus direct radiation (EC93).

Solar Spectrum Weights and Radiation Fractions for Surface Albedo						
Month	Wavelength Band (µm)				Diff. Rad. (DR) Fraction	Direct Rad. (1 – DR) Fraction
	0.25 - 0.69	0.69 - 1.19	1.19 - 2.38	2.38 - 4.00		
Jan	0.520	0.343	0.129	0.008	0.779	0.221

Feb	0.520	0.343	0.129	0.008	0.779	0.221
Mar	0.503	0.343	0.142	0.012	0.658	0.342
Apr	0.492	0.339	0.153	0.016	0.489	0.511
May	0.504	0.338	0.144	0.014	0.581	0.419
Jun	0.527	0.340	0.124	0.009	0.724	0.276
Jul	0.545	0.315	0.130	0.010	0.698	0.302
Aug	0.539	0.321	0.130	0.010	0.715	0.285
Sep	0.517	0.339	0.134	0.010	0.717	0.283
Oct	0.519	0.343	0.130	0.008	0.790	0.210
Nov	0.520	0.343	0.129	0.008	0.779	0.221
Dec	0.520	0.343	0.129	0.008	0.779	0.221

392   The albedo is then given as (*e.g.*, EC93),

393    $\alpha = (DR)\left(\Sigma_{j=1}^{4} w_j \alpha_{j(DR)}\right) + (1 - DR)\left(\Sigma_{j=1}^{4} w_j \alpha_{j(1-DR)}\right),$ (47)

394   where w_j is the weight of a given wavelength band, α_j is the albedo in that band, DR refers to the fraction of diffuse

395   radiation, and $(1 - DR)$ refers to the fraction of direct radiation. Table 3 summarizes the albedo values as functions

396   of the wavelength band of the incoming shortwave radiation spectrum, the surface type, direct or diffuse radiation,

397   and ice and snow thickness, and is reproduced here from Table 2 in EC93.

398   **Table 3.** Spectral albedos for the various surface types, reproduced here from Table 2 in EC93.

Spectral Albedos for Five Surface Types				
Surface Type	**Wavelength Band (µm)**			
	0.25 - 0.69	**0.69 - 1.19**	**1.19 - 2.38**	**2.38 - 4.00**
Dry snow, α_s				
Direct Rad.	0.980 - 0.008μ_0	0.902 - 0.116μ_0	0.384 - 0.222μ_0	0.053 - 0.047μ_0
Diffuse Rad.	0.975	0.832	0.250	0.025
Melting snow, α_s				
$h_s \geq 0.1$m	0.871	0.702	0.079	0.010
$h_s < 0.1$m	linearly reduced to bare sea ice value	linearly reduced to bare sea ice value	linearly reduced to bare sea ice value	linearly reduced to bare sea ice

				value
Bare sea ice, α_i				
$h_i < 1\text{m}$	$0.760 + 0.140\ln(h_i)$	$0.247 + 0.029\ln(h_i)$	0.055	0.036
$1\text{m} \le h_i < 2\text{m}$	$0.770 + 0.018(h_i - 1)$	$0.247 + 0.196(h_i - 1)$	0.055	0.036
$h_i \ge 2\text{m}$	0.778	0.443	0.055	0.036
Meltwater pond, α_p	$0.150 + \exp(-8.1h_p - 0.47)$	$0.054 + \exp(-31.8h_p - 0.94)$	$0.033 + \exp(-2.6h_p - 3.82)$	0.030
Open water/leads, α_w				
Direct Rad.	$\alpha_w* + 0.008$	$\alpha_w* - 0.007$	$\alpha_w* - 0.007$	$\alpha_w* - 0.007$
Diffuse Rad.	0.060	0.060	0.060	0.060

399   In Table 3, h_s is snow depth (m), and the value α_w^* is defined as (*e.g.*, EC93),

400     $$\alpha_w^* = \frac{0.026}{\mu_0^{1.7} + 0.065} + 0.015(\mu_0 - 0.1)(\mu_0 - 0.5)(\mu_0 - 1.0). \tag{48}$$

401   **2.2.7 Energy balance and thickness changes over snow and ice**

402   The energy balance at the surface of the snow or snow-free ice layer is represented by (*e.g.*, EC93),

403     $$(F_{net})_0 = \epsilon(F_{LW} - \sigma T_0^4) + (1 - \alpha)(1 - I_0)F_{SW} - F_{sens} - F_{lat} = -(F_c)_0, \tag{49}$$

404   where ϵ is the emissivity of the snow or ice (0.99), T_0 is the temperature of the snow or ice surface (K), α is the

405   snow or ice albedo, and $(F_c)_0$ is the conductive heat flux at the snow or ice surface (W m^{-2}). Eq. (49) is used to solve

406   for the snow or snow-free ice surface temperature after the first time-step.

407   Changes in snow and ice thickness are governed by the energy balances at the snow and ice surfaces and the base of

408   the ice, and the volumetric heats of fusion for snow and ice. The rate of change in snow thickness at the surface is

409   given by (*e.g.*, EC93),

410     $$\left(\frac{\partial h_s}{\partial t}\right)_0 = \frac{-F_{net} - (F_c)_0}{L_{fs}}, \tag{50}$$

411   where L_{fs} is the volumetric heat of fusion for snow (1.097×10^8 J m^{-3}). Similarly, the rate of change in thickness at

412   the surface of the snow-free ice is given by (*e.g.*, EC93),

413     $$\left(\frac{\partial h_i}{\partial t}\right)_0 = \frac{-F_{net} - (F_c)_0}{L_{fi}}, \tag{51}$$

414   where L_{fi} is the volumetric heat of fusion for ice (3.014×10^8 J m^{-3}). Changes in thickness at the ice surface are

415   constrained to be $\left(\frac{\partial h_i}{\partial t}\right)_0 \le 0$ so that ice growth only occurs through accretion at the base. The accretion or melting

416   at the base of the ice is defined by (*e.g.*, EC93),

417 $\left(\frac{\partial h_i}{\partial t}\right)_b = \frac{(F_c)_b - F_b}{L_{fb}},$ (52)

418 where $(F_c)_b$ is the conductive heat flux at the base of the ice (W m^{-2}), and L_{fb} is the volumetric heat of fusion for ice

419 at the base (2.679×10^8 J m^{-3}).

2.3 Dynamic model description

421 The dynamic model is based on the Smoothed Particle Hydrodynamics (SPH) formulation as originally applied to

422 ice dynamics in Gutfraind and Savage, 1997 and Lindsay and Stern, 2004. The dynamic model is coupled to the

423 thermodynamic model, and is run at each time-step immediately after the thermodynamic model. It is forced by

424 surface wind speed and direction, surface current speed and direction, Coriolis deflection, the horizontal gradient of

425 the sea surface slope, internal ice stresses, and a coastal boundary force. As per Lindsay and Stern, 2004, particles

426 which drift within 0.4 of the initial grid spacing are combined into a single particle.

2.3.1 Air drag

428 The zonal and meridional components of the acceleration (m s^{-2}) on each Lagrangian ice particle due to wind forcing

429 are given by,

430 $\overrightarrow{A_{wx}} = (\frac{1}{\rho_i h_i})\rho_a C_a \sqrt{(\overrightarrow{u_a} - \overrightarrow{u_i})^2 + (\overrightarrow{v_a} - \overrightarrow{v_i})^2}(\overrightarrow{u_a} - \overrightarrow{u_i}),$

431 $\overrightarrow{A_{wy}} = (\frac{1}{\rho_i h_i})\rho_a C_a \sqrt{(\overrightarrow{u_a} - \overrightarrow{u_i})^2 + (\overrightarrow{v_a} - \overrightarrow{v_i})^2}(\overrightarrow{v_a} - \overrightarrow{v_i}),$ (53)

432 respectively, where C_a is the dimensionless air drag coefficient (2.0×10^{-3}), $\overrightarrow{u_a}$ and $\overrightarrow{u_i}$ are the zonal velocities for

433 wind and ice drift, respectively, and $\overrightarrow{v_a}$ and $\overrightarrow{v_i}$ are the meridional velocities for wind and ice drift, respectively (m s^{-1}

434).

2.3.2 Water drag

436 The zonal and meridional components of the acceleration (m s^{-2}) on the ice particles due to ocean current forcing are

437 similar to those for the wind and are given by,

438 $\overrightarrow{A_{ox}} = (\frac{1}{\rho_i h_i})\rho_{wo} C_w \sqrt{(\overrightarrow{u_w} - \overrightarrow{u_i})^2 + (\overrightarrow{v_w} - \overrightarrow{v_i})^2}(\overrightarrow{u_w} - \overrightarrow{u_i}),$

439 $\overrightarrow{A_{oy}} = (\frac{1}{\rho_i h_i})\rho_{wo} C_w \sqrt{(\overrightarrow{u_w} - \overrightarrow{u_i})^2 + (\overrightarrow{v_w} - \overrightarrow{v_i})^2}(\overrightarrow{v_w} - \overrightarrow{v_i}),$ (54)

440 respectively, where ρ_{wo} is the density of seawater (kg m^{-3}), C_w is the dimensionless water drag coefficient (5.0×10^{-3}

441), and $\overrightarrow{u_w}$ and $\overrightarrow{v_w}$ are the zonal and meridional velocities for the surface current, respectively (m s^{-1}). The density of

442 seawater is computed by (*e.g.*, Fofonoff and Millard Jr., 1983),

443 $\rho_{wo} = 999.842594 + 6.793952 \times 10^{-2}T_w - 9.09529 \times 10^{-3}T_w^2 + 1.001685 \times 10^{-4}T_w^3 - 1.120083 \times$

444 $10^{-6}T_w^4 + 6.536332 \times 10^{-9}T_w^5 + (8.24493 \times 10^{-1} - 4.0899 \times 10^{-3}T_w + 7.6438 \times 10^{-5}T_w^2 - 8.2467 \times$

445     $10^{-7}T_w^3 + 5.3875 \times 10^{-9}T_w^4)S + (-5.72466 \times 10^{-3} + 1.0227 \times 10^{-4}T_w - 1.6546 \times 10^{-6}T_w^2)S^{1.5} + 4.8314 \times$

446     $10^{-4}S^2,$ (55)

447   where T_w is the SST (°C).

2.3.3 Coriolis deflection

449   The zonal and meridional components of the acceleration (m s^{-2}) on the ice particles due to Coriolis forcing are
450   given by,

451     $\overrightarrow{A_{cx}} = f\overrightarrow{v_i},$

452     $\overrightarrow{A_{cy}} = -f\overrightarrow{u_i},$ (56)

453   respectively. In Eq. (56), f is the Coriolis parameter (s^{-1}) and is defined by $2\omega_e\sin(\phi)$, where ω_e is the Earth
454   angular speed (7.292115×10^{-5} rad s^{-1}).

2.3.4. Sea surface gradient forcing

456   The zonal and meridional components of the horizontal gravitational acceleration (m s^{-2}) on the ice particles due to
457   the sea surface gradient are given by,

458     $\overrightarrow{A_{gx}} = -g\overrightarrow{\nabla H_x},$

459     $\overrightarrow{A_{gy}} = -g\overrightarrow{\nabla H_y},$ (57)

460   respectively, where $\overrightarrow{\nabla H_x}$ and $\overrightarrow{\nabla H_y}$ are the zonal and meridional gradients of the sea surface.

2.3.5. Internal ice stresses

462   The first step in calculating the internal ice stresses is to project the ice particle positions from their latitude-
463   longitude grid onto a Cartesian grid in order to facilitate computations of distance between the particles. The
464   northing-easting grid chosen for this work is the Mercator projection. Conversions of latitude and longitude to
465   Mercator northing, y, and easting, x, coordinates (m) are defined by,

466     $y = R_e k ln\left(\tan\left(\frac{\pi}{4} + \frac{\phi}{2}\right)\right),$

467     $x = R_e kL,$ (58)

468   respectively, where R_e is the radius of the earth (6371×10^3 m), k is the scale factor for 55°N latitude (1.75), and L is
469   the longitude (radians).

470   The zonal and meridional components of the acceleration (m s^{-2}) on the ice particles due to internal stress gradients
471   are given by (*e.g.*, Lindsay and Stern, 2004),

472     $\overrightarrow{A_{sx}} = \left(\frac{1}{\rho_i h_i}\right)\left(\frac{\partial \sigma_{xx}}{\partial x} + \frac{\partial \sigma_{xy}}{\partial y}\right),$

$$\overrightarrow{A_{sy}} = \left(\frac{1}{\rho_i h_i}\right)\left(\frac{\partial \sigma_{yy}}{\partial y} + \frac{\partial \sigma_{xy}}{\partial x}\right), \tag{59}$$

473

474 respectively, where σ is the internal ice stress tensor (kg s^{-2}). The components of the stress gradients $\frac{\partial \sigma_{xx}}{\partial x}$, $\frac{\partial \sigma_{yy}}{\partial y}$, $\frac{\partial \sigma_{xy}}{\partial x}$,

475 and $\frac{\partial \sigma_{xy}}{\partial y}$ are computed by first calculating the components of the stress tensor at the ice particle positions and then

476 linearly interpolating these values to four points surrounding each ice particle (Figure 6).
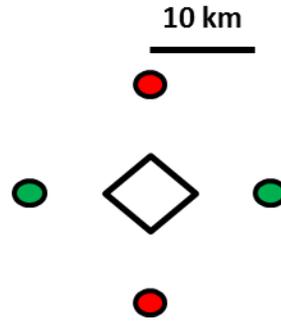

477

478 **Figure 6.** Schematic of the locations at which the ice stress tensor components are computed for calculation of the
479 stress gradients. The white diamond represents an ice particle, the green circles represent the locations between
480 which the zonal stress gradients are computed, and the red circles represent the locations between which the
481 meridional stress gradients are computed. The stress gradient length scale is 10 km (image is slightly altered from
482 original version in Lindsay and Stern, 2004).

483 In Figure 6, an ice particle is represented by the white diamond. The zonal components of the stress gradients, $\frac{\partial \sigma_{xx}}{\partial x}$

484 and $\frac{\partial \sigma_{xy}}{\partial x}$, are computed by finite differencing of the stress tensor values at the green circles, and the meridional

485 components of the stress gradients, $\frac{\partial \sigma_{yy}}{\partial y}$ and $\frac{\partial \sigma_{xy}}{\partial y}$, are computed by finite differencing of the stress tensor values at

486 the red circles.

487 The values of the stress tensor (kg m s^{-2}) are calculated as follows for each ice particle (*e.g.*, Gutfraind and Savage,
488 1997),

489 $$\sigma_{xx} = P_i - 2\eta\left(\dot{\epsilon}_{xx} - 0.5\left(\dot{\epsilon}_{xx} + \dot{\epsilon}_{yy}\right)\right),$$

490 $$\sigma_{yy} = \frac{\sigma_{xx}(1-\sin(\phi_i))}{1+\sin(\phi_i)},$$

491 $$\sigma_{xy} = -2\eta\dot{\epsilon}_{xy}, \tag{60}$$

492 where P_i is the internal ice pressure (N m^{-2}), η is the ice viscosity (kg m^{-1} s^{-1}), $\dot{\epsilon}_{xx}$, $\dot{\epsilon}_{yy}$, and $\dot{\epsilon}_{xy}$ are the components

493 of the strain rate tensor (s^{-1}), and ϕ_i is the internal ice friction angle (approximately 17.5°). The evaluation of σ_{yy} as

494 a function of the other principal stress component, σ_{xx}, satisfies the Mohr-Coulomb yield criterion for a plastic

495 regime as per Gutfraind and Savage, 1997. In Eq. (60), the pressure is taken as the ice compressive strength as per

496 Hibler III, 1979 and Sayed et al., 2002 and is defined as,

497 $$P_i = P^* h_i e^{-20(1-A_{ice})},\tag{61}$$

498 where P^* is a sea ice strength constant (5.0×10^3 N m^{-2}). The ice viscosity is defined as (*e.g.*, Gutfraind and Savage,
499 1997),

500 $$\eta = \min\left(\frac{P_i\,\sin(\phi_i)}{\dot{\epsilon}_{xx} - \dot{\epsilon}_{yy}}, \eta_{max}\right),\tag{62}$$

501 where η_{max} is the maximum possible value of the ice viscosity (1.0×10^{11} kg m^{-1} s^{-1}).

502 The components of the strain rate tensor are evaluated using the SPH formulation. While the strain rates for any
503 given ice particle are theoretically influenced by all other ice particles in the model domain, it is most
504 computationally practical to assume only a limited number of nearest-neighbor ice particles influence the strain rates
505 of a given particle. In this paper, only the nearest three ice particles are considered when calculating strain rates for a
506 given particle. Coastal boundary particles are considered when finding the nearest-neighbor particles, and their
507 influence on the strain rates of nearby ice particles is treated the same as that from other ice particles. However,
508 coastal cells have fixed zero-velocities and are assumed to be constantly circular with a radius of 5 km. They also
509 exert an additional repulsive force on ice particles (see section 2.3.6).

510 The influence that a given ice particle exerts on another decreases exponentially with distance between particles, and
511 is most commonly represented through the Gaussian kernel. The two-dimensional Gaussian kernel is defined as
512 (*e.g.*, Gutfraind and Savage, 1997),

513 $$W(\boldsymbol{r}, L) = \frac{1}{\pi L^2} e^{-\frac{r^2}{L^2}},\tag{63}$$

514 where $\boldsymbol{r}$ is the distance from the ice particle for which the strain rates are being calculated to a nearest-neighbor
515 particle (m), and L is a smoothing length (150 km as per Lindsay and Stern, 2004). The components of the strain rate
516 tensor are then given as (*e.g.*, Gutfraind and Savage, 1997),

517 $$\dot{\epsilon}_{xx} = \Sigma_k\left(-\frac{2 I_{area_k}(u_k - u_i) W(\boldsymbol{r}, L)_k r_{x_k}}{L^2}\right),$$

518 $$\dot{\epsilon}_{yy} = \Sigma_k\left(-\frac{2 I_{area_k}(v_k - v_i) W(\boldsymbol{r}, L)_k r_{y_k}}{L^2}\right),$$

519 $$\dot{\epsilon}_{xy} = \Sigma_k\left(\frac{-I_{area_k}(v_k - v_i) W(\boldsymbol{r}, L)_k r_{y_k} - I_{area_k}(u_k - u_i) W(\boldsymbol{r}, L)_k r_{x_k}}{L^2}\right),\tag{64}$$

520 where I_{area_k} is the total surface are of the kth nearest-neighbor ice particle (m^2), u_k and v_k are the zonal and
521 meridional velocities of the kth nearest-neighbor ice particles, respectively (m s^{-1}), u_i and v_i are the zonal and
522 meridional velocities of the ice particle for which the strain rate tensor is being calculated, respectively (m s^{-1}), and
523 r_{x_k} and r_{y_k} are the zonal and meridional distances from the ice particle for which the strain rates are being
524 calculated to the kth nearest-neighbor particle (m). The surface areas of the ice particles are calculated at each time-
525 step using Voronoi tessellation over the whole model domain as per Lindsay and Stern, 2004. For each ice particle,
526 the Voronoi polygon covers the area surrounding the particle which is closer to that particle than to any other.

2.3.6 Coastal boundary force

In order to prevent ice particles from drifting past the coastal boundary cells, a repulsive force from each coastal cell is exerted on every ice particle in the direction of the vector pointing from the coastal cell toward the ice particle. As per Lindsay and Stern, 2004, the force is given in the form $\frac{1}{R^2}$, where R is the distance from the coastal cell to the ice particle. The force is set to be 0.1 N m^{-2} at a distance of 25 km. An identical repulsion force is also exerted on ice particles from the boundaries of the model domain in the ocean in order to keep ice particles from drifting outside the model domain.

2.3.7 Dynamic evolution of ice thickness and concentration

Changes in the ice thickness and concentration of particles due to dynamics are determined by the principal components of the strain rate tensor as follows,

$$\frac{\partial h_i}{\partial t} = -h_i\left(\dot{\epsilon}_{xx} + \dot{\epsilon}_{yy}\right),$$

$$\frac{\partial A_{ice}}{\partial t} = -A_{ice}\left(\dot{\epsilon}_{xx} + \dot{\epsilon}_{yy}\right), \tag{65}$$

respectively. The dynamically induced changes in ice thickness and concentration are then added to any thermodynamically induced changes in these parameters at each time-step.

2.4 Time-stepping schemes

Several numerical integration schemes for time-stepping are used in the present model. The Euler-forward scheme (*e.g.*, Khandekar, 1980) is used to solve the thermodynamic equations for changes in snow and ice thickness (Eqs. 50-52), changes in snow and ice temperature due to solar radiation penetration (Eqs. 18, 20-21), and snow accumulation. This scheme is used to calculate changes from the first to second time-step in melt-pond depth (Eq. 22), water temperature beneath the base of the ice (Eq. 29), and lead area fraction (Eq. 27). The Euler-forward scheme is additionally used in the dynamic model to integrate the ice particle velocities to position displacements, to update the dynamically forced changes in ice thicknesses and concentrations (Eq. 65), and to integrate the initial ice accelerations to velocities from the first time-step to the second. The Euler-forward scheme is represented by,

$$X_{i+1} = X_i + \Delta t \left(\frac{\partial F}{\partial t_i}\right) : i = 1, \tag{66}$$

where X is the variable being solved, i is the time-step index, Δt is the time-step (seconds), and F is the function of X differentiated with respect to time, t.

The second-order Adams-Bashforth scheme (*e.g.*, Khandekar, 1980) is used to solve thermodynamic equations for changes in melt-pond depth (Eq. 22), water temperature beneath the base of the ice (Eq. 29), and lead area fraction (Eq. 27) from the second to the fourth time-steps. This scheme is also used to solve the changes in ice particle velocities from the second to the fourth time-steps in the dynamic model. The second-order Adams-Bashforth scheme is represented by,

558      $X_{i+1} = X_i + \Delta t \left(1.5 \frac{\partial F}{\partial t_i} - 0.5 \frac{\partial F}{\partial t_{i-1}} \right) : 1 < i \leq 3.$ (67)

559   The fourth-order Adams-Bashforth scheme (*e.g.*, Matthews and Fink, 2004) is used to solve for changes in melt-

560   pond depth (Eq. 22), water temperature beneath the base of the ice (Eq. 29), and lead area fraction (Eq. 27) from the

561   fourth time-step onward in the thermodynamic model. In the dynamic model, the fourth-order Adams-Bashforth

562   predictor-corrector scheme (*e.g.*, Matthews and Fink, 2004) is used to solve the ice velocity changes from the fourth

563   time-step onward. The fourth-order Adams-Bashforth predictor-corrector scheme is represented by,

564      $X_{i+1} = X_i + \frac{\Delta t}{24} \left(55 \frac{\partial F}{\partial t_i} - 59 \frac{\partial F}{\partial t_{i-1}} + 37 \frac{\partial F}{\partial t_{i-2}} - 9 \frac{\partial F}{\partial t_{i-3}} \right),$

565      $X_{i+1} = X_i + \frac{\Delta t}{24} \left(9 \frac{\partial F}{\partial t_{i+1}} + 19 \frac{\partial F}{\partial t_i} - 5 \frac{\partial F}{\partial t_{i-1}} + \frac{\partial F}{\partial t_{i-2}} \right) : i > 3,$ (68)

566   where the first line represents the fourth-order Adams-Bashforth scheme, and both lines represent the sequential

567   steps of the combined predictor-corrector scheme.

568   The one-dimensional heat equations for the snow and ice temperatures (Eqs. 1 and 7) in the thermodynamic model

569   are solved using the standard Euler-forward scheme and centred finite-differencing for second-order differential

570   equations between the first and second time-steps, and the Dufort-Frankel algorithm (*e.g.*, EC93 and Mitchell and

571   Griffiths, 1980) from the second time-step onward. The Euler-forward scheme with centred finite-differencing is

572   represented by (*e.g.*, MacKinnon, 2015),

573      $X_{i+1}^j = X_i^j + \frac{\kappa \Delta t}{\Delta z^2} \left(X_i^{j+1} - 2X_i^j + X_i^{j-1} \right) : i = 1,$ (69)

574   where j is the depth level index in the snow or ice layer, κ is the quotient of the thermal conductivity and the

575   volumetric heat capacity for snow or ice, and Δz is the spacing between depth levels (m). The Dufort-Frankel

576   algorithm is represented by (*e.g.*, MacKinnon, 2015),

577      $X_{i+1}^j = \left(\frac{1-\beta}{1+\beta} \right) X_{i-1}^j + \left(\frac{\beta}{1+\beta} \right) \left(X_i^{j+1} + X_i^{j-1} \right),$ (70)

578   where β represents the quantity $2 \frac{\kappa \Delta t}{\Delta z^2}$.

579   Acceptable numerical stability of the integration schemes is achieved when a time-step Δt of one hour (3600

580   seconds) is used for the thermodynamic model-only runs, and a time-step of one minute (60 seconds) is used for the

581   thermodynamic-dynamic coupled model runs.

582   **2.5 Model input**

583   The atmospheric inputs to the model include the 2 m air and dew-point temperatures, relative humidity, 10 m wind

584   speed and direction, surface pressure, total cloud cover area fraction, snowfall, and total precipitation. All

585   atmospheric parameters except for precipitation are taken from the North American Regional Reanalysis (NARR),

586   which has an approximately 0.3° spatial resolution (about 33.3 km) and a three-hourly temporal resolution. In order

587 to make the wind speed more realistic for near surface winds, a logarithmic wind profile law is used to scale the 10

588 m height wind speeds to 2 m (*e.g.*, ISO 19901-1),

589 $$U_a = U_{a_{10m}}\left(1 + 0.0573\sqrt{1 + 0.15U_{a_{10m}}}\right)\ln\left(\frac{2}{10}\right),$$ (71)

590 where $U_{a_{10m}}$ is the NARR wind speed at 10 m (m s^{-1}).

591 The snowfall and total precipitation data are given in meters of water equivalent over the dataset time-step and are

592 taken from the European Centre for Medium-Range Weather Forecasting (ECMWF) ERA-Interim Reanalysis,

593 which has a 0.5°-0.75° spatial resolution (about 55.5-83 km) and a six-hourly temporal resolution. Rainfall is

594 assumed to be the difference of the total precipitation and the snowfall. In order to convert the ECMWF snowfall

595 data from meters of water equivalent to actual snow accumulation, SF, the following relationship to 2 m air

596 temperature is used (*e.g.*, NWS, 1996),

597 $SF = 5SF_w, T_a \geq 0,$

598 $SF = 10SF_w, 0 > T_a \geq -1.1,$

599 $SF = 15SF_w, -1.1 > T_a \geq -3.9,$

600 $SF = 20SF_w, -3.9 > T_a \geq -7.8,$

601 $SF = 30SF_w, -7.8 > T_a \geq -11.1,$

602 $SF = 40SF_w, -11.1 > T_a \geq -15,$

603 $SF = 50SF_w, T_a < -15,$ (72)

604 where SF_w is the snowfall rate in meters of water equivalent (m s^{-1}), and T_a is in °C.

605 The ice and oceanographic inputs to the model include the sea surface temperature, sea surface salinity, surface

606 current speed and direction, sea surface height above the geoid, and sea ice thickness, concentration, and drift speed

607 and direction. The ice and oceanographic parameters are taken from the Operational Mercator global Ocean analysis

608 and forecast system. This dataset has a 0.08° spatial resolution (approximately 8.9 km), a two-hourly temporal

609 resolution for sea surface temperature, sea surface salinity, and surface current speed and direction, and a daily-mean

610 temporal resolution for sea surface height above the geoid, and sea ice thickness, concentration, and drift speed and

611 direction. In this dataset, the sea surface temperature, salinity, currents, and height are initially derived from the

612 Nucleus for European Models of the Ocean (NEMO 3.1), while the sea ice thickness, concentration, and velocity are

613 derived from the LIM2 sea ice model. Sea surface height anomaly data derived from the Jason2, Cryosat, and Saral-

614 Altika satellites are assimilated into the dataset, as well as sea surface temperature data from the Reynolds AVHRR-

615 AMSR ¼° satellite, and in-situ profiles of ocean temperature and salinity. The sea ice thickness, concentration, and

616 velocity are used to initialize the model, while the remaining metocean parameters described above are used to force

617 the model for the duration of a run.

618 Finally, the Labrador coastal boundaries are included, and well as the ocean bathymetry (*e.g.*, GEBCO, 2008, 30-
619 second data). All dynamic input data are spatially and temporally linearly interpolated as needed.

2.6 Comparison of LIM2 sea ice data with CIS ice charts

621 Given the fact that the LIM2 sea ice dataset used here to initialize the model and compare model results to the "best
622 estimate" of sea ice conditions is itself derived from a model, it is worth comparing the LIM2 ice data from the
623 current model run period of April-May 2015 for the Labrador coast with observations from the CIS ice charts. The
624 LIM2 dataset was used in this study due to its relatively high temporal (daily) resolution compared to the weekly-
625 mean resolution of the CIS digitized ice charts. Figure 7-Figure 15 show the normalized errors between the weekly
626 average CIS chart and the LIM2 ice concentration and thickness for April-May 2015 for central coastal Labrador
627 from Makkovik north to Nain. Here, the normalized (dimensionless) error is defined as,

628 $$E_{C,T} = \frac{CIS_{C,T} - LIM2_{C,T}}{CIS_{C,T}}, \tag{73}$$

629 where $CIS_{C,T}$ is the ice concentration (0-1) or thickness (m) of a given domain grid point from the CIS chart, and
630 $LIM2_{C,T}$ is the ice concentration (0-1) or thickness (m) of the same grid point from the LIM2 dataset.

631 Figure 7-Figure 15 show that the LIM2 dataset is fairly close to the CIS charts in terms of ice concentration and
632 thickness for this period in the areas of the model domain closer to shore. The LIM2 dataset simulates greater ice
633 concentrations and thicknesses further offshore than the CIS charts show. However, the present paper focuses on
634 simulating ice conditions close to the Labrador coast from near Makkovik up to Nain; hence the LIM2 dataset can
635 be considered reliable for the purposes of this study. Note that the LIM2 model does not simulate the land-fast ice
636 cover directly along the shoreline, whereas the CIS charts show the land-fast ice. However, in this paper, the break-
637 up of the land-fast ice is assumed to occur when the deployed buoys began to drift.
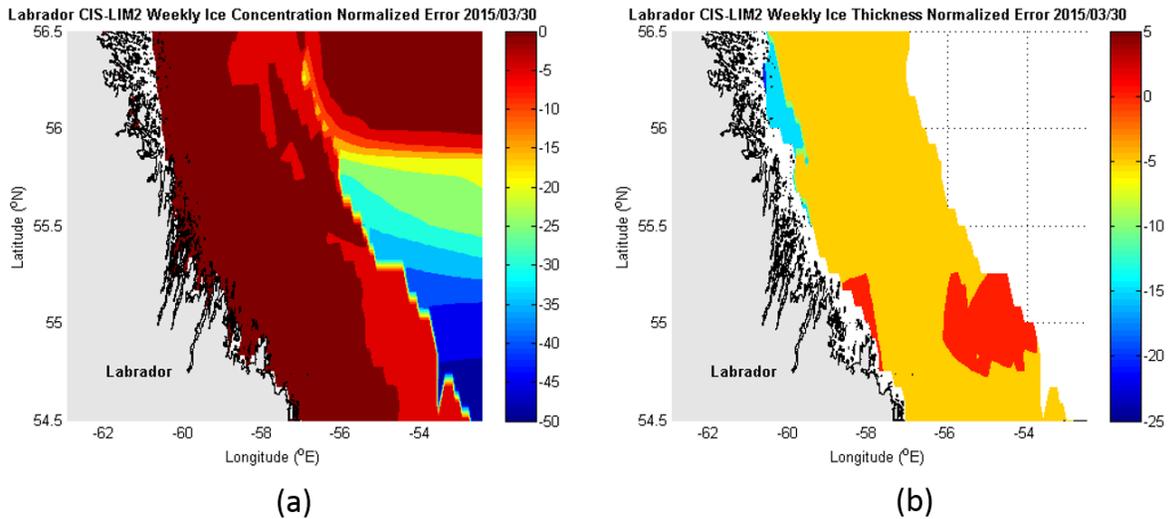

638

3 Model Validation

In this section, results of model runs are presented for the thermodynamic model for April 1 – May 31, 2015, as well as runs of the coupled thermodynamic-dynamic model for May 1-7, 2015. The thermodynamic model run period was selected to cover the observed break-up periods for the land-fast ice offshore Makkovik and Nain. Two of the three ice drift tracking buoys deployed offshore Makkovik began to drift on April 23 (Figure 1), and each of the three buoys deployed offshore Nain began to drift on May 1, 2, and 6, respectively. The shorter thermodynamic-

671 dynamic model run period was selected to cover most of the observed break-up period for the land-fast ice offshore
672 Nain.

673 The model runs are initialized with the best estimate of sea ice conditions over the model domain as obtained from
674 the LIM2 sea ice model dataset, and model results here are compared with the LIM2 data. Hereafter, all results from
675 the model presented in this paper are referred to as "model" results, and data from the LIM2 dataset are referred to
676 explicitly. The model domain extends between 62°W and 57.5°W longitude and 55°N and 57°N latitude. For the
677 thermodynamic model-only runs, the parameters of interest which are presented here are the sea ice thickness and
678 concentration. For the thermodynamic-dynamic model, the sea ice thickness, concentration, and velocity are
679 presented. Of particular interest in the present work is the model performance in the regions offshore Makkovik and
680 Nain; hence, additional analyses are given for the temporal evolution of sea ice thickness and concentration in these
681 areas.

682 The thermodynamic model runs use a 0.45° spatial resolution (approximately 50 km) for initial ice particle spacing
683 and a one-hourly temporal resolution, while the thermodynamic-dynamic model run uses a 0.5° spatial resolution
684 (approximately 55.5 km) for initial ice particle spacing and a one-minute temporal resolution. The higher temporal
685 resolution is needed for the stability of the numerical integration scheme in the dynamic model. Hence, a lower
686 spatial resolution and shorter model run period are used for the dynamic model to lessen the required computation
687 time.

688 **3.1 Thermodynamic model results**

689 The largest uncertainty in the thermodynamic model is the initialization of snow cover on the sea ice. While
690 available reanalysis datasets provide snow depth, they only provide it in meters of water equivalent; however, actual
691 snow depth on the sea ice plays a critical role in the evolution of the ice cover due to the strong insulating effect of
692 snow. Since there do not exist any widespread and frequent snow depth measurements along the Labrador coast, an
693 approximate early spring mean snow depth value of 40 cm is used here to initialize the model on April 1. This depth
694 was taken from measurements of snow depth performed on Lake Melville in March 2009 (*e.g.*, Prinsenberg et al.,
695 2011). It cannot be overstated how uncertain this initial snow depth value is, as it is applied to the entire model
696 domain, and snow depths may be significantly greater further north around Nain. Future use of this model for
697 operational ice forecasting purposes must involve adequate snow depth data acquisition.

698 In the model results presented here, one model run assumes 40 cm of snow depth over the entire model domain at
699 the start of April 1, 2015, while another model run assumes no snow on the sea ice at the start of the model run on
700 April 1. Both model runs are subject to the same snow accumulation on the ice over the two-month period as forced
701 by the ECMWF snowfall data. Hence, the effect of a significant snow cover on the ice at the start of the melt season
702 can be examined.

703 Figure 16 shows the initial ice conditions on April 1, 2015 00:00 UTC as given by the LIM2 dataset. The green
704 circle represents the region offshore Makkovik analyzed here, and the purple circle represents the region offshore
705 Nain. There are four model grid points within each of these circled regions over which ice thickness and

706 concentrations are averaged for the offshore Makkovik and Nain analyses. These two regions were selected to
707 encompass the land-fast ice in the vicinities of Makkovik and Nain so that the timing of the land-fast ice break-up
708 could be modeled and compared with the actual timing of the break-up as recorded by the ice tracking buoys.

(a)   (b)
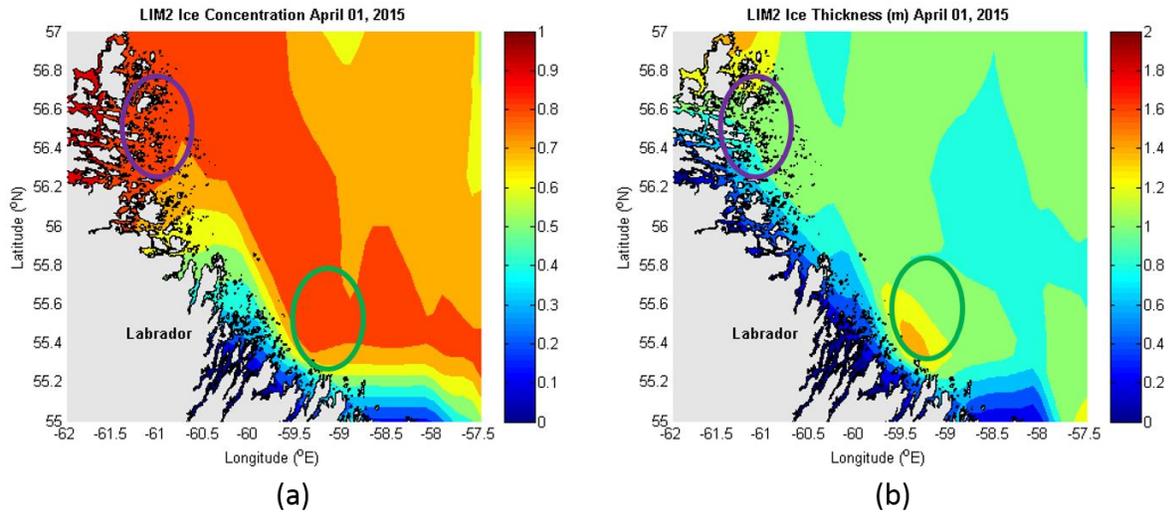

709

710 **Figure 16.** Sea ice concentration (a) and thickness (b) over the model domain at the start of the thermodynamic
711 model runs on April 1, 2015 00:00 UTC, as obtained from the LIM2 dataset. The region circled in green represents
712 the area over which ice conditions offshore Makkovik are analyzed in this section, and the purple circled region
713 represents the area over which ice conditions offshore Nain are analyzed.

714 Figure 17 shows the evolution of average ice conditions during April 1 – May 31, 2015 in the regions offshore
715 Makkovik (green circles in Figure 16) and Nain (purple circles in Figure 16) according to the LIM2 data, the
716 thermodynamic model with 40 cm of initial snow cover, and the thermodynamic model with no initial snow cover.
717 According to the model run with initial snow cover, the average ice thickness and concentration offshore Makkovik
718 decrease to zero on May 14, while for the run with no initial snow cover, the ice disappears completely around
719 Makkovik on May 1. The progression of the LIM2 ice thickness and concentration near Makkovik shows a
720 somewhat less precipitous decline in ice conditions compared to the model results shown here. While the LIM2 ice
721 thickness and concentration do not reach zero during the model time period, they decline to less than 0.2 m and 0.1,
722 respectively, by May 18 before rebounding slightly as more ice drifts into the region from the north. This minimum
723 in overall average ice conditions offshore Makkovik occurs four days after the model minimum with 0.4 m initial
724 snow cover, and 18 days after the disappearance of ice in the model run with no initial snow cover. In the region
725 offshore Nain, the ice also disappears on May 14 in the model with initial snow cover, and on April 25 in the model
726 without initial snow cover (Figure 17). The LIM2 ice thickness and concentration decrease to zero by May 15.
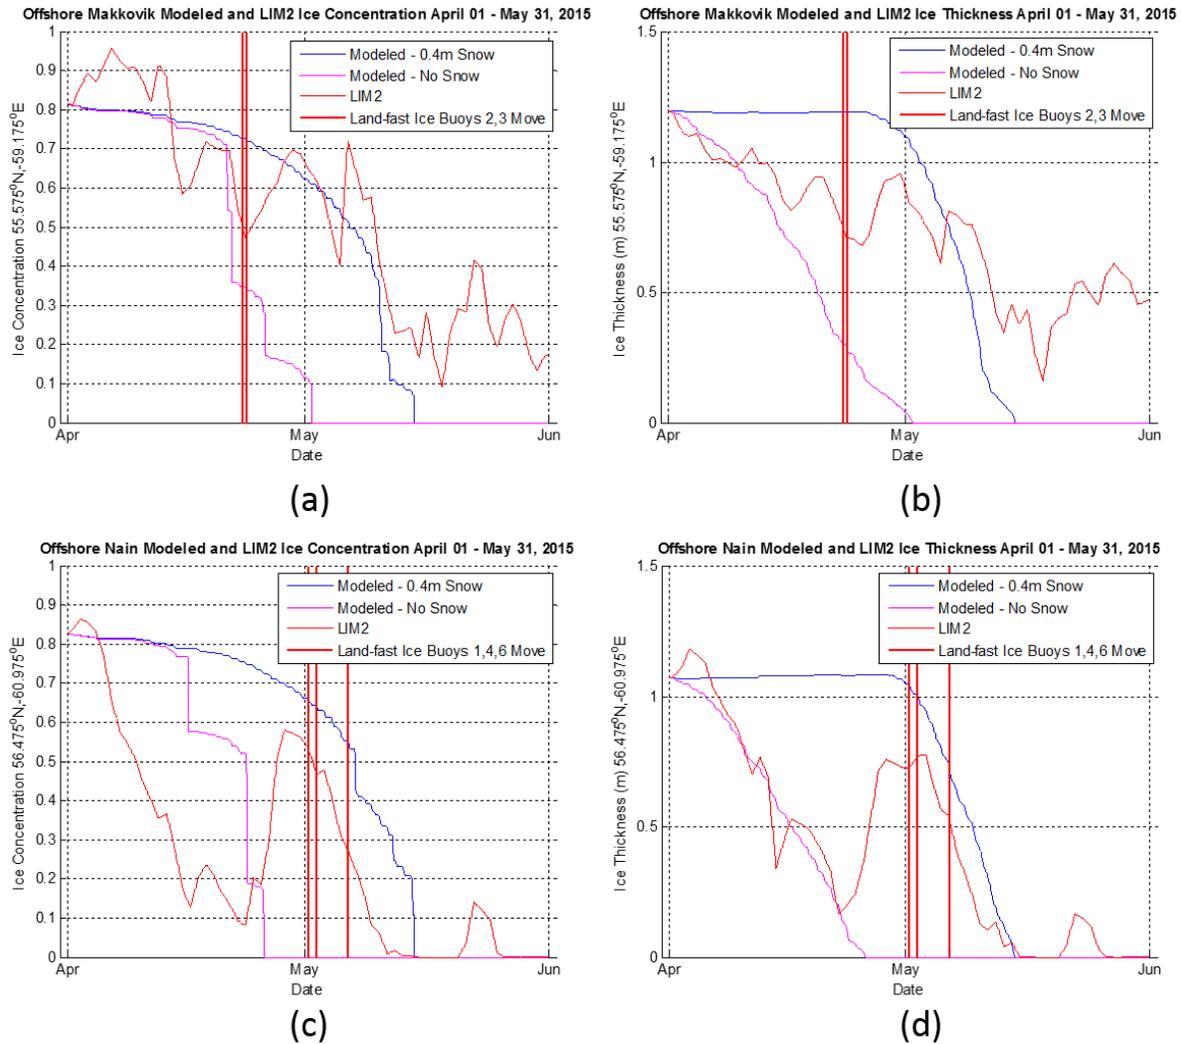

Figure 17. Evolution of average ice concentration (a,c) and thickness (b,d) in the focus regions offshore Makkovik (a,b) and Nain (c,d) during April 1 – May 31, 2015. The thin red lines represent LIM2 ice conditions, the blue lines represent ice conditions for the thermodynamic model presented here initialized with 40 cm of snow, and the magenta lines represent ice conditions for the thermodynamic model initialized with no snow. The thick red lines mark the timing of first recorded movement by the land-fast ice buoys. The latitude-longitude coordinates shown on the y-axes represent the central locations for the regions over which average ice conditions are shown.

The thick red lines in Figure 17 mark the times that the land-fast ice buoys first recorded movement, indicating that the break-up of the land-fast ice in those regions had begun. Buoys 2 and 3 began to drift on April 23 around 05:00 and 15:00 UTC, respectively, offshore Makkovik, and buoys 1, 4, and 6 began to drift around May 1 10:00, May 2 12:00, and May 6 12:00 UTC, respectively, offshore Nain. The model run with 40 cm initial snow cover most accurately predicts the timing of the onset of the land-fast ice break-up with precipitous declines in regional mean ice thickness and concentration commencing immediately after these times. The averaged results for both the Makkovik and Nain regions suggest that there was most likely significant snow cover on the ice on April 1, and that

741   if the model is properly initialized with snow cover conditions, it can reasonably predict the progression and timing

742   of the decline in regional ice concentration and thickness more than a month in advance.

743   At the specific locations at which the ice drift buoys were deployed, Figure 18 shows the modeled ice concentrations

744   and thicknesses near Makkovik and Nain for April 1 – May 31 from the thermodynamic model with 0.4 m of initial

745   snow cover. This model run is not initialized with the LIM2 ice concentration and thickness data, but rather assumes

746   the land-fast ice at these five locations had a concentration and thickness of 0.995 and 0.95 m on April 1,

747   respectively. The assumed ice thickness represents the mean of the normal thickness range for medium first-year ice

748   (0.7-1.2 m), which was the ice type shown for these locations on April 1 on the CIS daily ice charts. In Figure 18,

749   the times at which the modeled ice concentrations first drop below 0.99 and the modeled thicknesses first began to

750   display steep decreases below their original thickness of 0.95 m are used as proxies for the beginning of the local of

751   land-fast ice break-up. These times fall within 4.7 hours to 5.9 days from the times at which the drift buoys began to

752   move at these locations (Table 4).

(d)

753
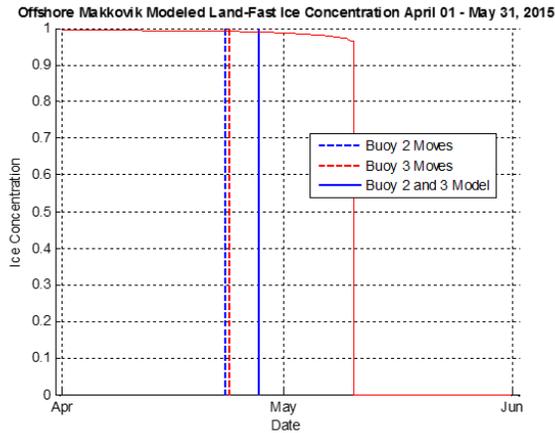

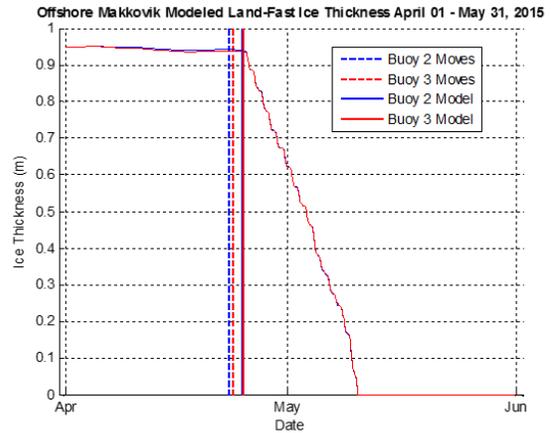

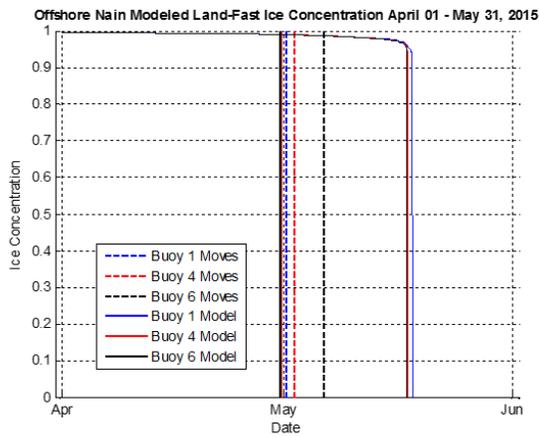

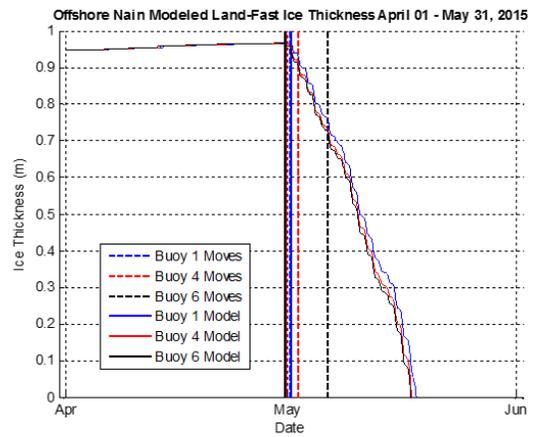

Figure 18. Modeled ice concentration and thickness (thin solid lines) vs. time at the buoy deployment locations near Makkovik (a,b) and Nain (c,d). The vertical dashed lines represent the times at which the buoys first recorded motion, the vertical solid lines represent the times at which the modeled ice concentrations begin to fall below 0.99 (a,c), and the times at which the modeled ice thicknesses first fall below 0.95 m (all times in UTC).

Table 4. Summary of buoy deployment locations, modeled and observed land-fast ice break-up times according to concentration and thickness criteria described above, and observed minus modeled break-up time error ranges.

Buoy	Deployment Coordinates	Modeled Break-Up Time (Thickness)	Modeled Break-Up Time (Concentration)	Observed Break-Up Time	Observed - Modeled Error Range (hours)
1	56.45°N, 60.78°W	May 01 14:00	April 30 17:00	May 01 09:18	-4.7 to 16.3

2	55.29°N, 59.24°W	April 24 21:00	April 27 14:00	April 23 04:32	-105.5 to -40.5
3	55.28°N, 59.19°W	April 25 02:00	April 27 14:00	April 23 14:14	-95.8 to -35.8
4	56.40°N, 60.80°W	April 30 20:00	April 30 16:00	May 02 11:26	39.4 to 43.4
6	56.39°N, 60.84°W	April 30 18:00	April 30 15:00	May 06 11:38	137.6 to 140.6

760   Figure 19 shows contour plots of the modeled and LIM2 ice thickness and concentration across the model domain
761   24 days into the model run, and one day after the first land-fast ice buoys offshore Makkovik began to drift. The
762   model results shown in Figure 19 are from the run initialized with 0.4 m of snow cover. The model shows little
763   change in ice thicknesses by April 24 compared to April 1, with some decrease in ice concentrations. The LIM2 data
764   show a comparatively more extensive retreat in ice thicknesses and concentrations by April 24; however, both the
765   LIM2 data and the model results show a large region of ice concentrations around 0.7 toward the coast, with
766   concentrations around 0.6 immediately to the east.

767
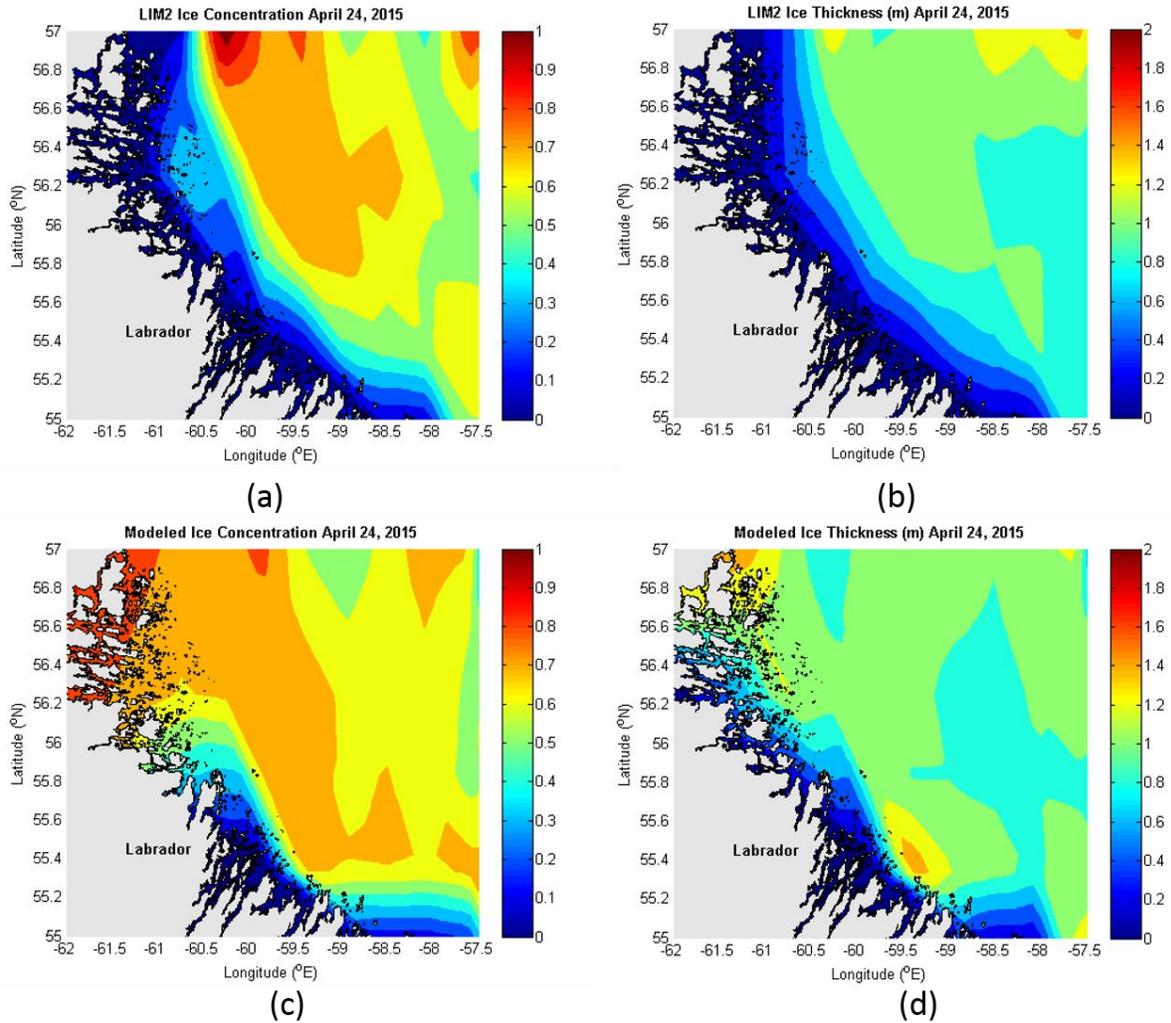

Figure 19. Sea ice concentration (a,c) and thickness (b,d) on April 24, 2015 03:00 UTC (00:00 AST) from LIM2 data (a,b) and the thermodynamic model presented here (c,d). The results of the thermodynamic model run shown here are initialized with 40 cm of snow.

The results in Figure 20 show that when the thermodynamic model is initialized with no snow cover on April 1, nearly all the ice disappears by April 24. In this model run, the ice disappears completely from the model domain by May 2, which indicates that it is not a realistic scenario to initialize the model without a snow cover.

(a)   (b)

774
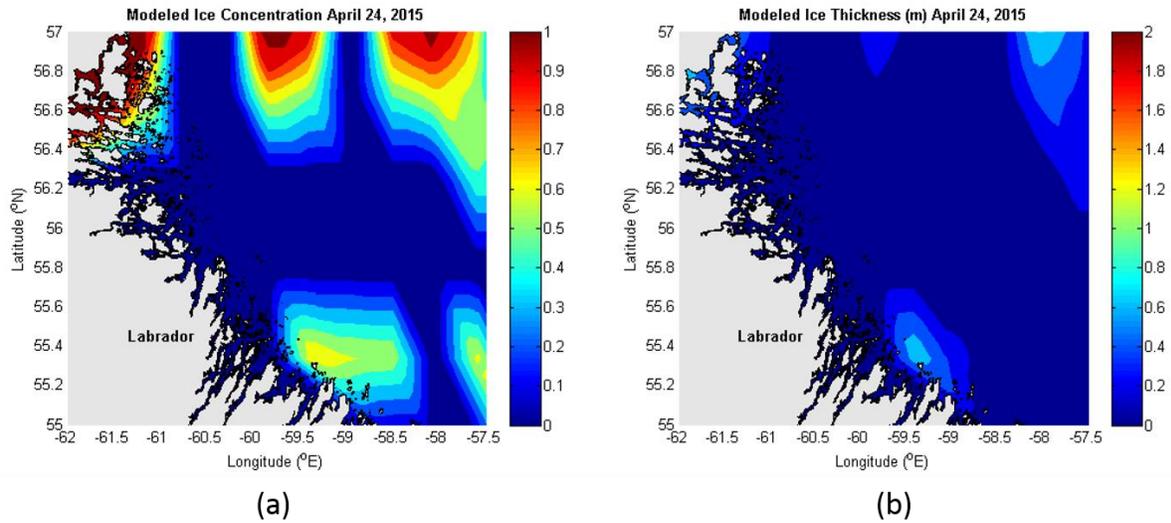

Figure 20. Sea ice concentration (a) and thickness (b) on April 24, 2015 03:00 UTC (00:00 AST) from the
thermodynamic model with no initial snow cover.

Figure 21-Figure 23 show contour plots of the modeled and LIM2 ice thickness and concentration across the model
domain for May 2, 3, and 7, respectively. These dates were selected to coincide with the timing of the first detected
motion of the land-fast ice buoys deployed offshore Nain. These buoys began to drift on May 1, 2, and 6. The model
results shown here are all from the run initialized with 0.4 m of snow cover. While the modeled results and LIM2
data show somewhat different patterns of ice retreat during the May 2-7 period, both show a general pattern of the
retreat of thicker, more concentrated ice toward the northern end of the model domain.
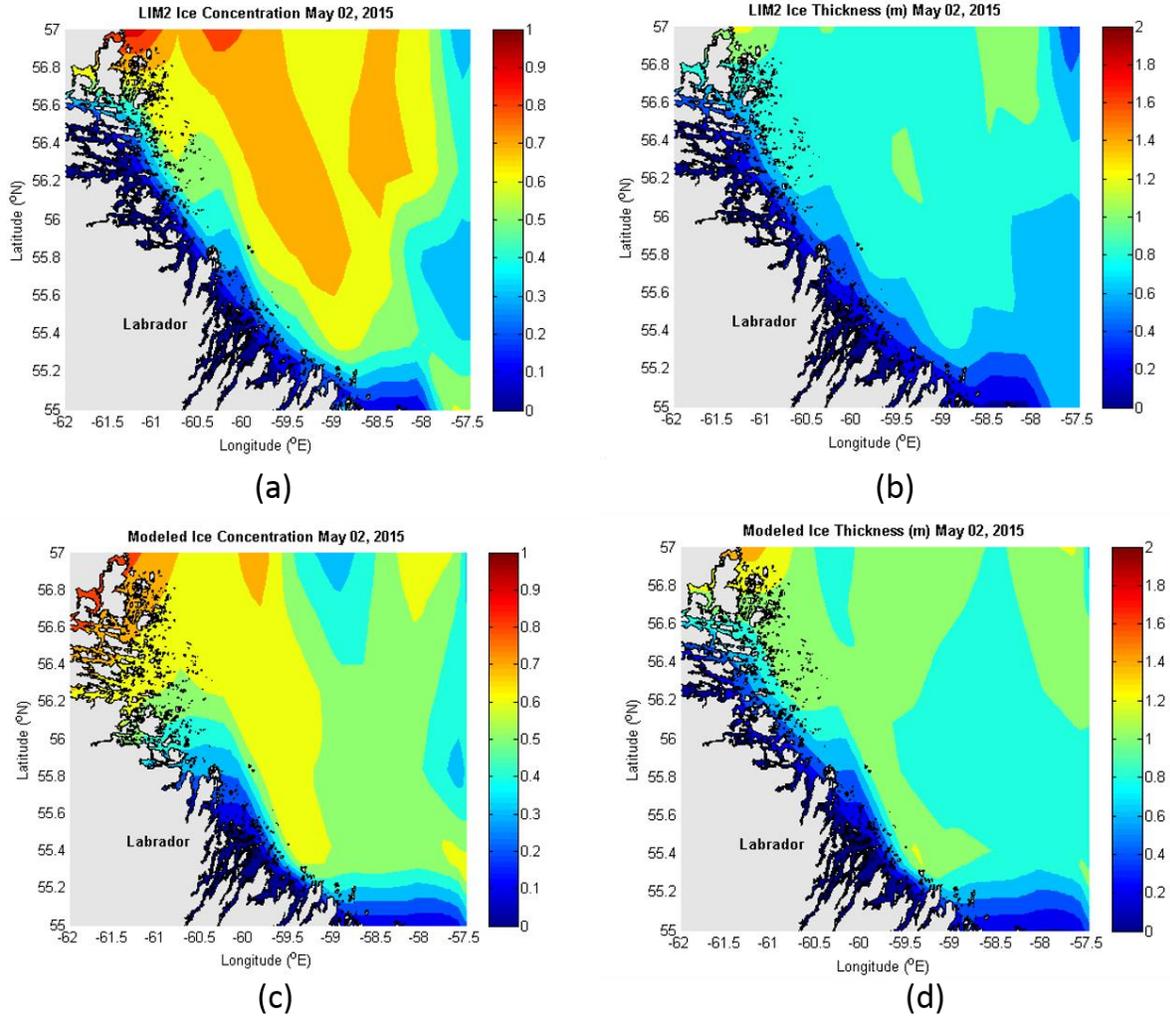

Figure 21. Sea ice concentration (a,c) and thickness (b,d) on May 02, 2015 03:00 UTC (00:00 AST) from LIM2 data (a,b) and the thermodynamic model presented here (c,d). The results of the thermodynamic model run shown here are initialized with 40 cm of snow.
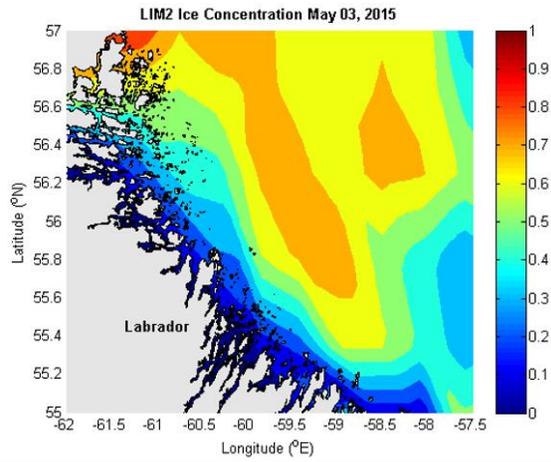

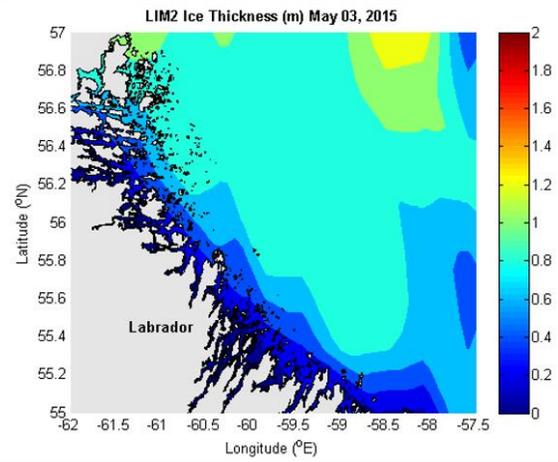

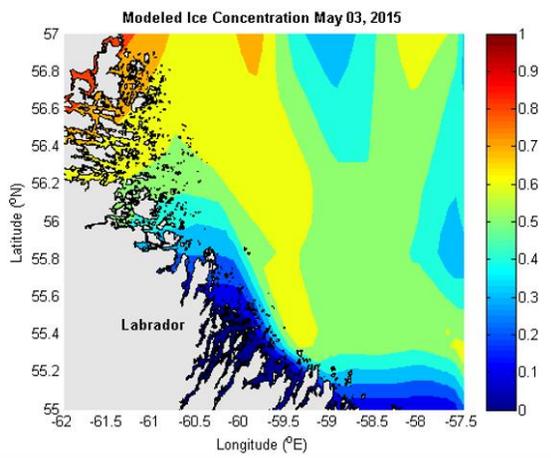

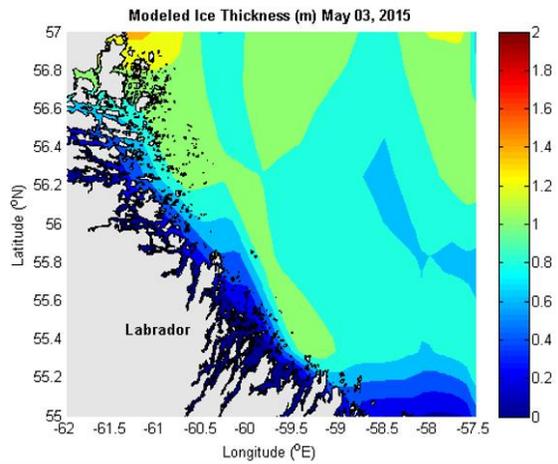

Figure 22. Sea ice concentration (a,c) and thickness (b,d) on May 03, 2015 03:00 UTC (00:00 AST) from LIM2 data (a,b) and the thermodynamic model presented here (c,d). The results of the thermodynamic model run shown here are initialized with 40 cm of snow.
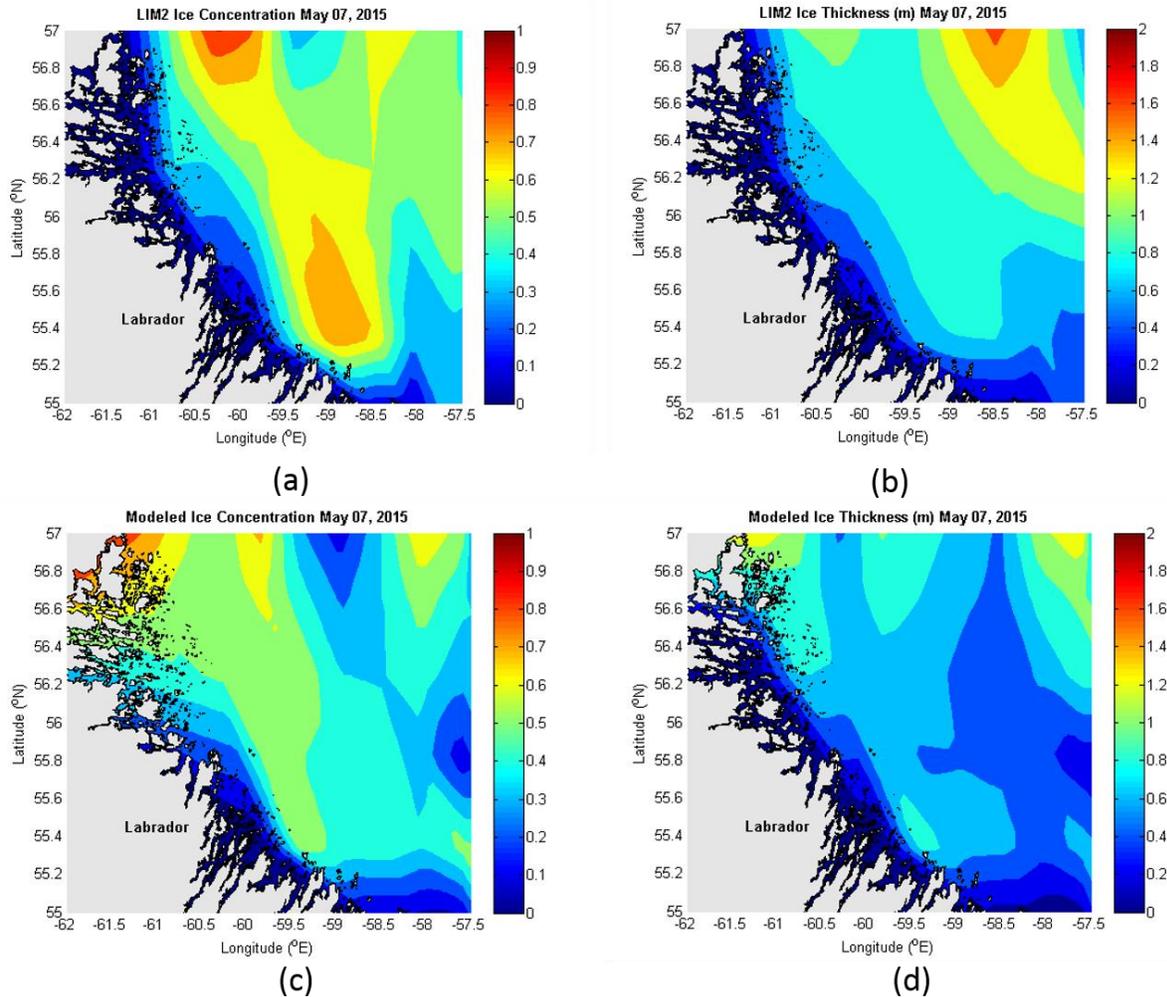

Figure 23. Sea ice concentration (a,c) and thickness (b,d) on May 07, 2015 03:00 UTC (00:00 AST) from LIM2 data (a,b) and the thermodynamic model presented here (c,d). The results of the thermodynamic model run shown here are initialized with 40 cm of snow.

Figure 24 shows the evolution of average ice conditions during April 1 – May 31, 2015 over the model domain according to the LIM2 data, the thermodynamic model with 40 cm of initial snow cover, and the thermodynamic model with no initial snow cover. The spatially averaged ice thickness and concentration for the model run with 0.4 m of initial snow cover tracks closely to the LIM2 mean thickness and concentration, and begins to decrease significantly on May 11 when both the mean thickness and concentration decrease to less than 0.5 (m or concentration). The ice disappears completely from the model domain on May 15. The spatially averaged ice thickness and concentration for the model run with no initial snow cover tracks closely to the LIM2 mean thickness and concentration, and begins to decrease significantly on April 21 when both the mean thickness and concentration decrease to less than 0.5 (m or concentration). In the model run with no initial snow cover, the ice disappears completely on May 1. The LIM2 mean domain ice thickness and concentration both remain fairly constant around

805   0.6 (m or concentration) during April 1 – May 11, and subsequently begin to display greater variability between 0.3-

806   0.7 (m or concentration) while showing an overall decrease, until May 31.

(a)   (b)
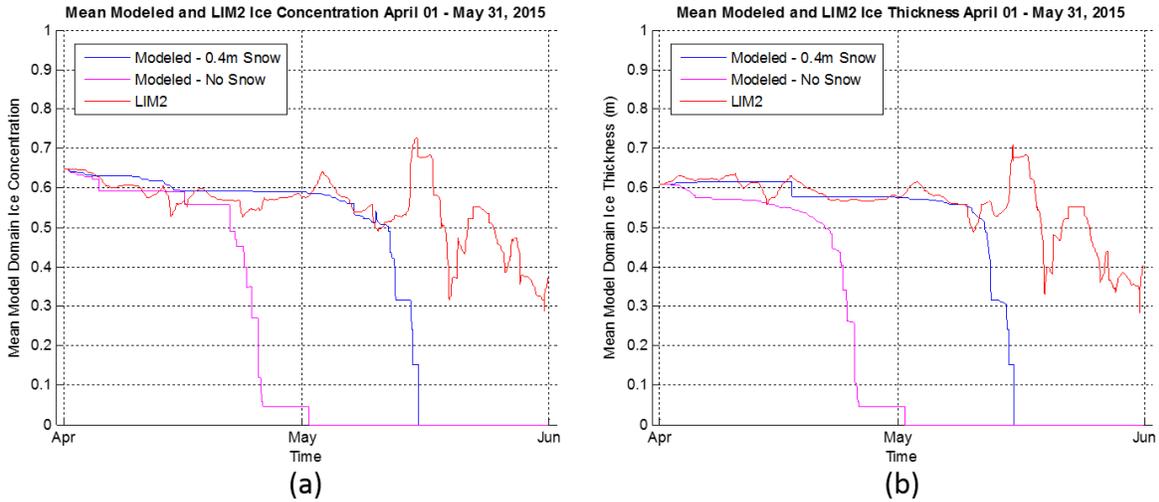

807

808   **Figure 24.** Evolution of average ice concentration (a) and thickness (b) over the entire model domain during April 1

809   – May 31, 2015. The red lines represent LIM2 ice conditions, the blue lines represent ice conditions for the

810   thermodynamic model presented here initialized with 40 cm of snow, and the magenta lines represent ice conditions

811   for the thermodynamic model initialized with no snow.

812   Table 5 summarizes the model domain mean ice thicknesses and concentrations for the selected dates shown in

813   Figure 19-Figure 23 for the LIM2 dataset, the model run with 0.4 m of initial snow cover, and the model run with no

814   initial snow cover.

815   **Table 5.** Summary of modeled vs. LIM2 model domain mean ice concentration and thickness for selected dates for

816   April 1 – May 31, 2015 model run.

Modeled vs. LIM2 Mean Domain Ice Concentration and Thickness (Thermodynamic Model)					
Date	April 01 Snow Cover (m)	LIM2 Concentration	Modeled Concentration	LIM2 Thickness (m)	Modeled Thickness (m)
April 24	0.40	0.42	0.57	0.43	0.48
	0.00		0.44		0.43
May 02	0.40	0.77	0.54	0.65	0.47

3.2 Thermodynamic-dynamic model results

The coupled thermodynamic-dynamic model run for May 1-7, 2015 is initialized with the LIM2 ice thickness, concentration, and velocity grid for May 1 00:00 UTC (Figure 25). The green circle represents the single coordinate offshore Makkovik analyzed here (55.25°N, 59.25°W), and the purple circle represents the coordinate offshore Nain (56.5°N, 61°W). Given that the ice particles are free to drift from their initial positions in the dynamic model, the modeled ice conditions at these coordinates are linearly interpolated.

(a)   (b)

824
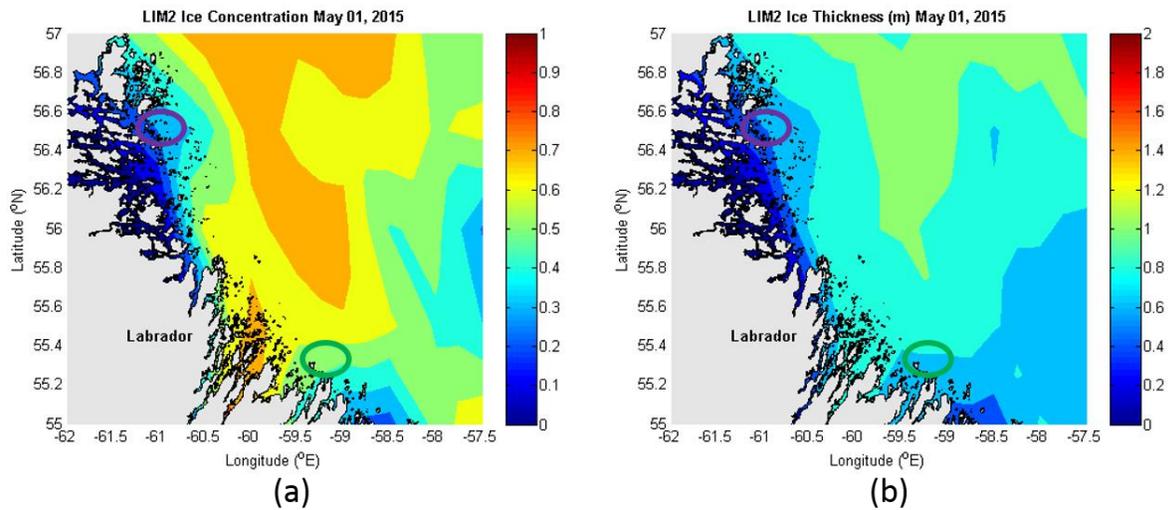

Figure 25. Sea ice concentration (a) and thickness (b) over the model domain at the start of the thermodynamic-dynamic model run on May 1, 2015 00:00 UTC, as obtained from the LIM2 dataset. The region circled in green represents the area over which ice conditions offshore Makkovik are analyzed in this section, and the purple circled region represents the area over which ice conditions offshore Nain are analyzed.

Figure 26 shows the evolution of modeled and the LIM2 ice thickness (a,c) and concentration (b,d) during May 1-7 offshore Makkovik (a,b) and Nain (c,d).

(a)

(b)

(c)

(d)

831
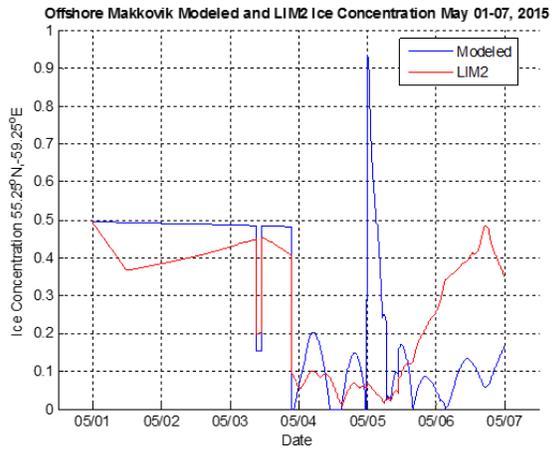

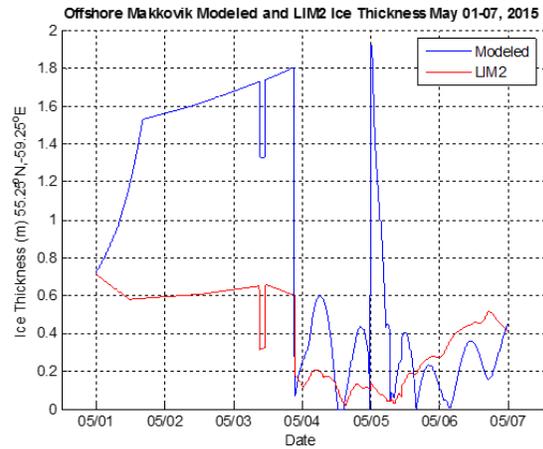

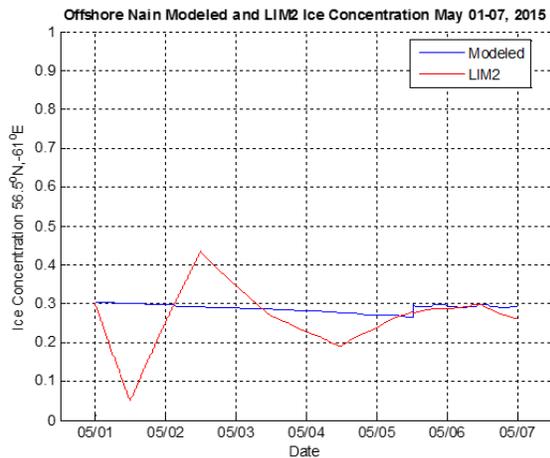

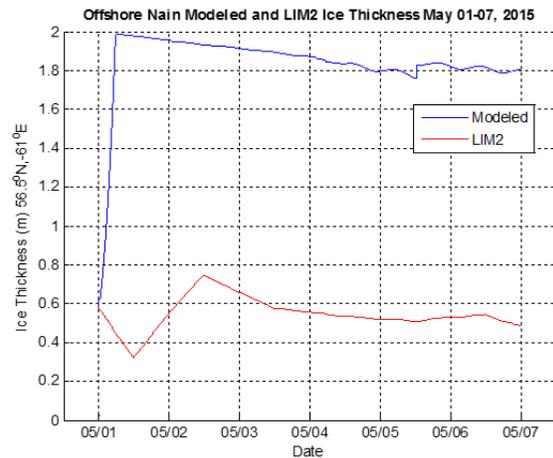

Figure 26. Evolution of average ice concentration (a,c) and thickness (b,d) in the focus regions offshore Makkovik (a,b) and Nain (c,d) during May 1-7, 2015. The red lines represent LIM2 ice conditions, and the blue lines represent ice conditions for the thermodynamic-dynamic model. The latitude-longitude coordinates shown on the y-axes represent the central locations for the regions over which average ice conditions are shown.

Figure 27-Figure 30 show the modeled ice drift velocities and total speeds along the trajectories of buoys 1-4 during May 1-7. The plots for buoy 4 begin on May 2 when the buoy began to record drift (Figure 30). Results for buoys 5-6 are not shown because buoy 5 remained stationary on the land-fast ice offshore Makkovik for its entire transmission period, and buoy 6 did not drift for more than 24 hours during the model run period. The results show that the model can reproduce mean regional ice drift velocities; however the model tends to underestimate high-frequency spikes in drift speeds compared to those recorded by the drift buoys 1 and 4 (Figure 27 and Figure 30). Along the track of buoy 1, the model does not capture the tidally-forced oscillations in the ice drift velocity as recorded by the buoy; this is most likely due to the inadequate spatial resolution of the NEMO 3.1 ocean current

-45-

844   input. For the along-track drift speeds of buoys 2 and 3, the model overestimates the increase in ice drift speeds
845   during May 3-7 (Figure 28-Figure 29).
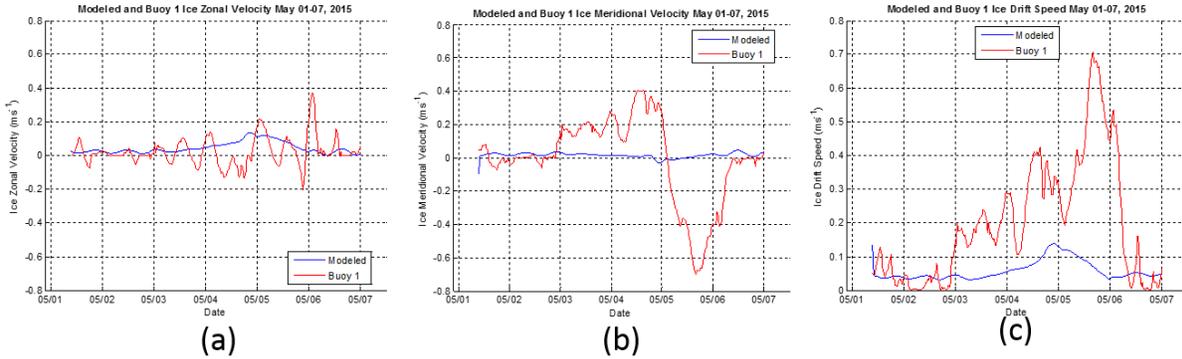

846

847   **Figure 27.** Modeled (blue lines) and buoy 1 measured (red lines) along-track ice drift zonal (a), meridional (b)
848   velocities, and speeds (c) during May 1-7, 2015 offshore Labrador.
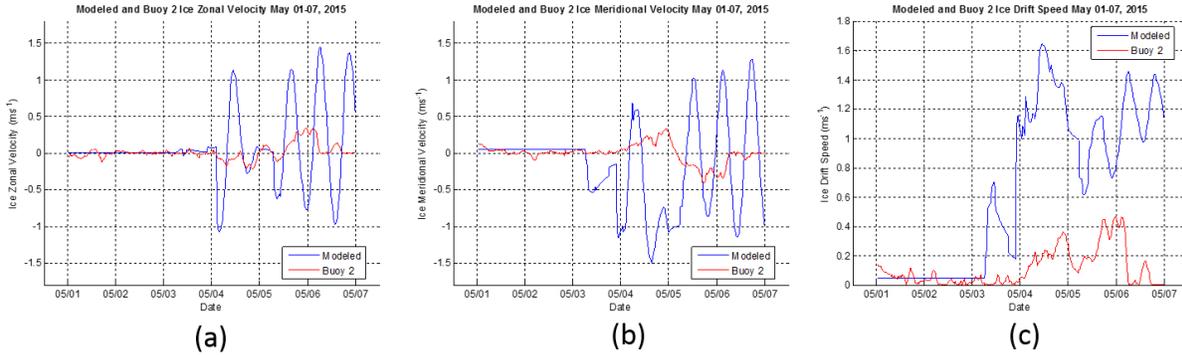

849

850   **Figure 28.** Modeled (blue lines) and buoy 2 measured (red lines) along-track ice drift zonal (a), meridional (b)
851   velocities, and speeds (c) during May 1-7, 2015 offshore Labrador.
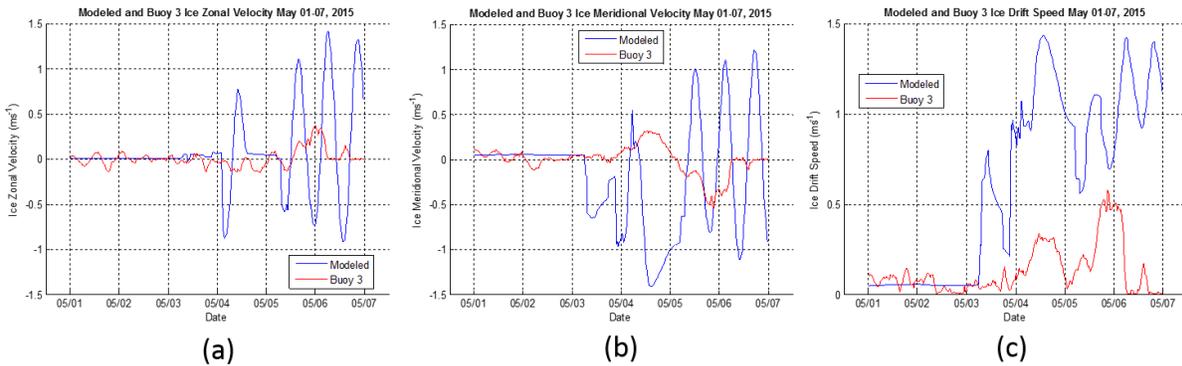

852

853   **Figure 29.** Modeled (blue lines) and buoy 3 measured (red lines) along-track ice drift zonal (a), meridional (b)
854   velocities, and speeds (c) during May 1-7, 2015 offshore Labrador.

(a)   (b)   (c)
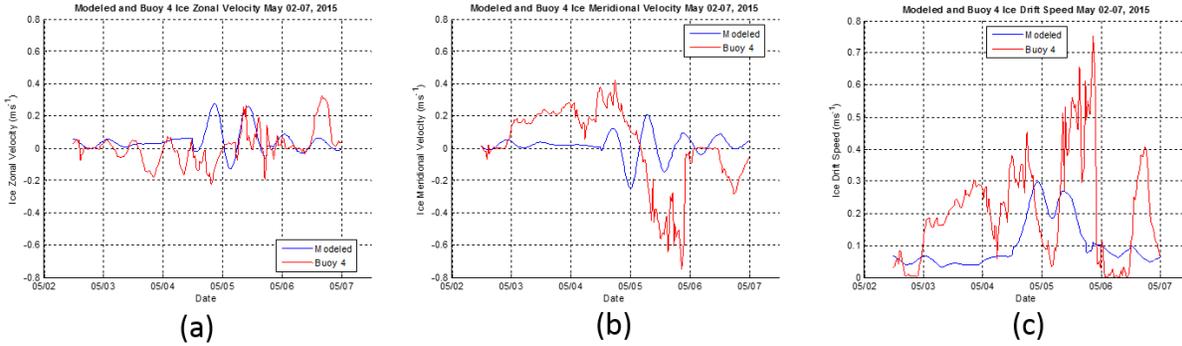

855

856   **Figure 30.** Modeled (blue lines) and buoy 4 measured (red lines) along-track ice drift zonal (a), meridional (b)

857   velocities, and speeds (c) during May 1-7, 2015 offshore Labrador.

858   Figure 31 shows the observed minus modeled ice drift speed errors during May 1-7 for buoys 1-4. The buoy-

859   recorded and modeled drift speeds were very close during May 1-3. For buoys 1 and 4, the observed-modeled drift

860   speed error increases to 0.2-0.5 m s^{-1} during May 3-7. For buoys 2 and 3, the observed-modeled drift speed error

861   increases to 0.5-1.5 m s^{-1} during this same period. These results indicate that the model is better at simulating

862   observed ice drift speeds further offshore compared to nearshore drift speeds, as buoys 1 and 4 drifted further

863   offshore than buoys 2 and 3 (see Figure 1). Beginning on May 3, the modeled ice velocities along the tracks of

864   buoys 2 and 3 increase significantly over the observed buoy-tracked ice velocities. This is due to increases in the

865   internal ice stresses, sea surface tilt forcing, and coastal boundary forcing along the nearshore tracks of buoys 2 and

866   3 in the model.

**Observed vs. Modeled Ice Drift Speed Error May 01-07, 2015**

867
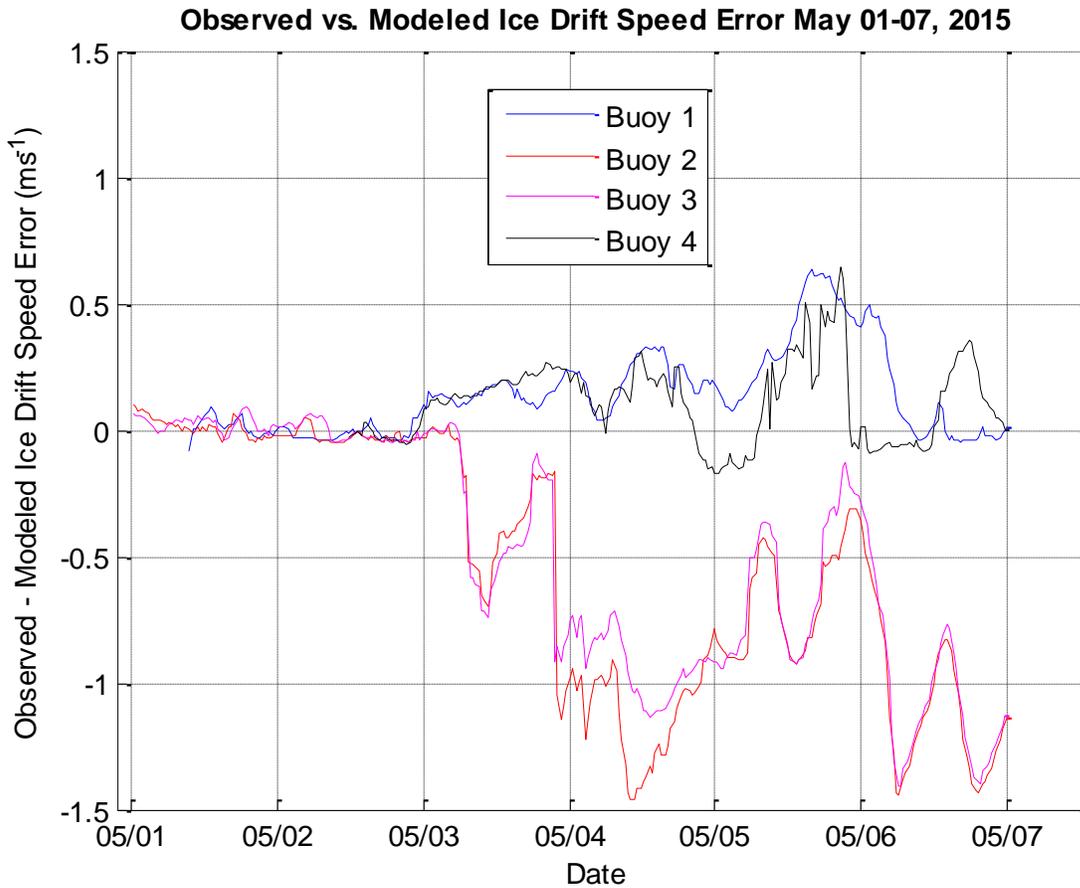

Figure 31. Observed minus modeled ice drift speeds along the trajectories of buoys 1-4 during May 1-7, 2015

offshore Labrador.

Figure 32-Figure 34 show the LIM2 and modeled ice thickness and concentrations for the model domain for May 3,

5, and 7, respectively. The model tends to overestimate ice thicknesses and concentrations across the domain;

however the model does capture the fact that a tongue of higher ice concentrations develops toward the middle of

the model domain.
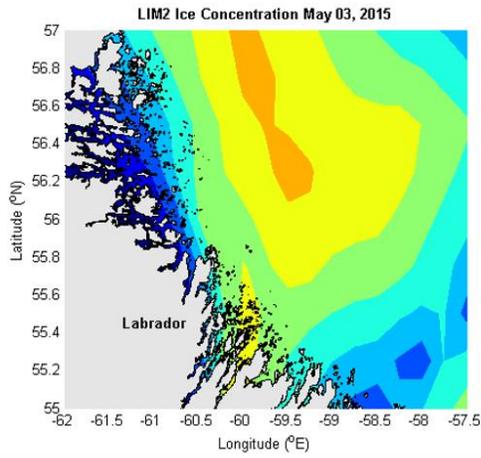

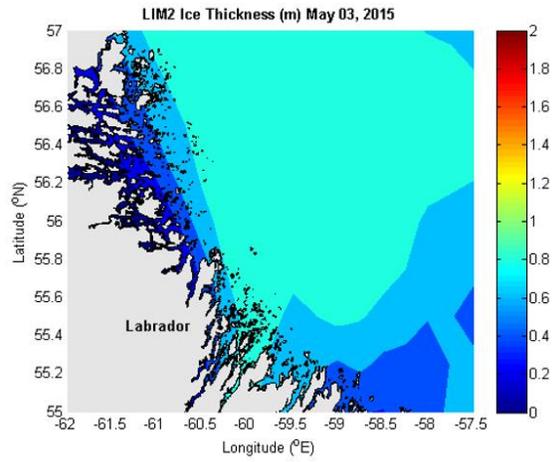

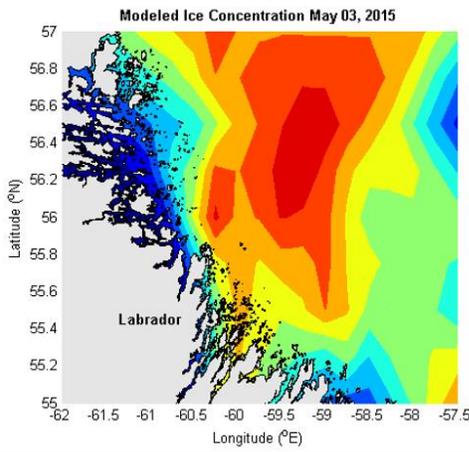

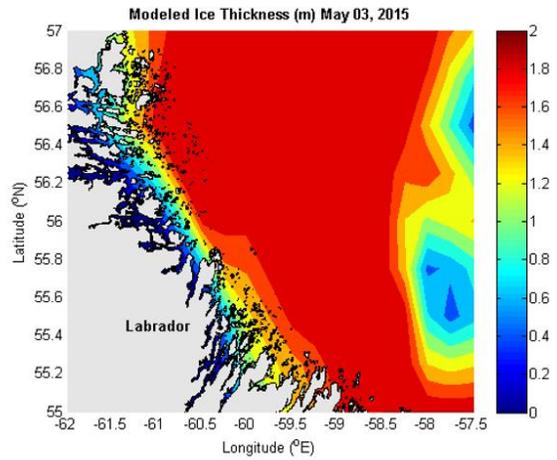

Figure 32. Sea ice concentration (a,c) and thickness (b,d) on May 03, 2015 03:00 UTC (00:00 AST) from LIM2 data (a,b) and the thermodynamic-dynamic model presented here (c,d).

877
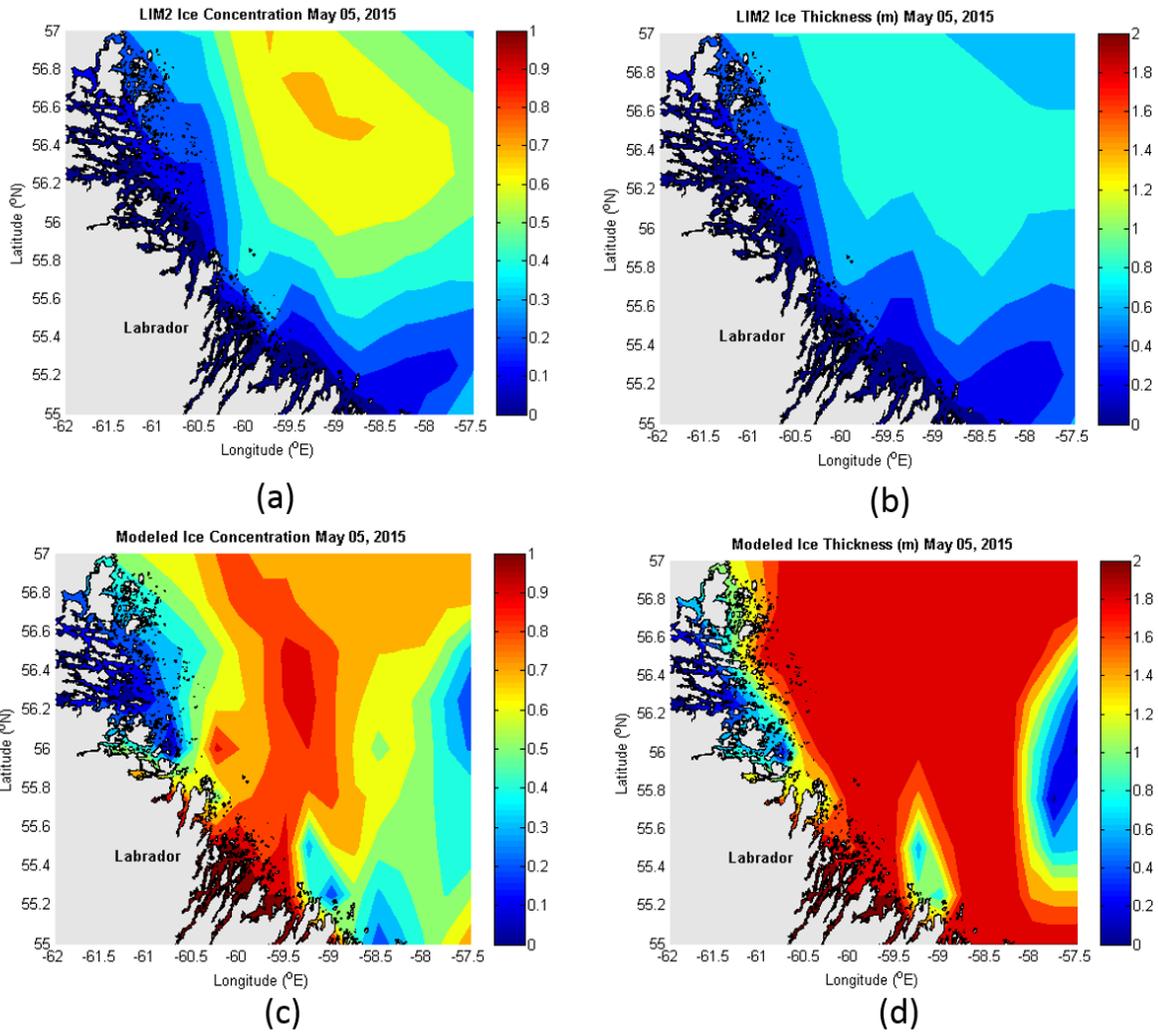

Figure 33. Sea ice concentration (a,c) and thickness (b,d) on May 05, 2015 03:00 UTC (00:00 AST) from LIM2 data (a,b) and the thermodynamic-dynamic model presented here (c,d).

886   **Figure 35.** Evolution of average ice concentration (a) and thickness (b) over the entire model domain during May 1-
887   7, 2015. The red lines represent LIM2 ice conditions, and the blue lines represent ice conditions for the
888   thermodynamic-dynamic model presented here.

889   Table 6 summarizes the mean model domain ice thicknesses and concentrations for the model and the LIM2 dataset
890   for the selected dates analyzed in this section.

891   **Table 6.** Summary of modeled vs. LIM2 model domain mean ice concentration and thickness for selected dates for
892   May 1-7, 2015 model run.

Modeled vs. LIM2 Mean Domain Ice Concentration and Thickness (Thermodynamic-Dynamic Model)				
Date	**LIM2 Concentration**	**Modeled Concentration**	**LIM2 Thickness (m)**	**Modeled Thickness (m)**
May 03	0.55	0.78	0.54	0.81
May 05	0.42	0.75	0.42	0.80
May 07	0.39	0.55	0.38	0.79

893   **4 Conclusions**

894   A model is presented in this paper which can be used to generate short-term (several days) to seasonal (months)
895   forecasts of regional ice conditions for coastal Labrador. It was shown that when the thermodynamic model was
896   used by itself for the April-May 2015 period, forecasts of the timing of the near-disappearance of ice near Makkovik
897   and Nain, Labrador were accurate to within one to four days when the model was initialized on April 1 (Figure 17).
898   For the specific locations on the land-fast ice at which the tracking buoys were originally deployed, the
899   thermodynamic model predicted the times at which the land-fast ice started to break-up accurately to within 4.7
900   hours to up to almost six days (Figure 18 and Table 4). However, these model results assumed a uniform snow cover

901   of 0.4 m on the sea ice on April 1 for the whole model domain of coastal Labrador. Given the extreme uncertainty of

902   this initial condition, it is imperative that operational use of this model utilize accurate measurements of snow cover

903   for the initialization of the model. It may be possible to hindcast initial snow depths by fitting the thermodynamic

904   model to seasonal evolutions of ice cover as documented by the CIS ice charts.

905   The thermodynamic model can be used to generate seasonal forecasts of the timing and spatial pattern of the break-

906   up of the land-fast ice along coastal Labrador. Such forecasts are important to operational planning for possible

907   future oil and gas exploration and production operations in this region, as well as vessel transport operations such as

908   those associated with the Voisey's Bay nickel mine. Access to ports near Makkovik and Nain is not possible for low

909   or non-ice class vessels prior to the break-up of the land-fast ice.

910   The coupled thermodynamic-dynamic model can be used to issue forecasts of the evolution of the coastal Labrador

911   ice cover over shorter periods of days to weeks compared to the thermodynamic-only model, which can help inform

912   the planning of ice management operations and vessel routing. The modeled ice drift speeds during May 1-7, 2015

913   were within 1.5 m s^{-1} of those measured by the tracking buoys deployed on the land-fast ice during April (Figure

914   31). Given the fact that the dynamic model does not account for ice entering or leaving the edges of the model

915   domain, the model should be run for as large an area as possible and for shorter periods, with the selected model

916   domain boundaries far away from particular locations of interest for ice forecasting. The temporal and spatial

917   resolution of the model can be adjusted by the user, with computational efficiency and model runtimes improving at

918   lower resolutions.

919   The model is most likely sensitive to a number of the thermodynamic and dynamic parameters such as the number

920   of nearest-neighbor ice particles and the smoothing length used in the SPH scheme, among others. Further study of

921   the model's sensitivity to these parameters is warranted. In addition, the thermodynamic model for prediction of the

922   onset of land-fast ice break-up does not account for the effects of wind stress. The wind speed in the current

923   thermodynamic model only affects the ice through the sensible and latent heat fluxes (Eqs. 32 and 39, respectively).

924   Future development of this model should account for the tensile stresses imposed on the offshore land-fast ice

925   boundary by the offshore component of the wind.

926   Finally, it is important to note that the results shown in this paper were generated with observed and hindcast

927   metocean data. Operational use of this model will require forecast metocean data, which will increase the errors in

928   the ice forecasts. However, the model can be reinitialized in near-real-time with the most up-to-date locally observed

929   gridded ice and metocean datasets in order to improve regional ice forecasts. Export of this model to other ice

930   environments is also an important aspect of this model development effort.

931   **Code and Data Availability**

932   Upon request to the lead author, the ice buoy drift data and model output raw data can be provided. The model code

933   is proprietary to C-CORE; however, for the review process, the model code can be made available temporarily to the

934   reviewers and journal editor. Upon request, all materials will be uploaded to a C-CORE FTP site with login details

935   provided.

936   **Author Contributions**

937   Ian Turnbull led the deployment of the ice tracking buoys, developed the model code, ran the simulations, and wrote

938   the paper. Rocky Taylor assisted with the deployment of the ice tracking buoys and helped revise the paper.

939   **Competing Interests**

940   The authors declare that they have no conflicts of interest.
