Referee comment on "How changing the height of the Antarctic ice sheet affects global climate: A mid-Pliocene case study" by Xiaofang Huang et al., Clim. Past Discuss., https://doi.org/10.5194/cp-2022-30-RC1, 2022

General comments

Huang et al. presented an interesting analysis of the global-scale effects of changes in ice sheet volume. It is useful to see the local, regional, and global changes in climate variables caused by reductions in the height of the east Antarctic Ice Sheet. The results were clearly and systematically presented. The methodological limitations of the model were nicely discussed and addressed.

However, it is unclear to me whether this is intended as an idealized study, or whether it seeks to replicate the effects of actual past and future changes in ice sheets. If the former, that should be made clear. If the latter, then there needs to be a much more robust discussion of the relevant past and/or future scenarios that are meant to be reproduced here. If these experiments are meant to investigate possible future changes in climate, then it would also be useful to see comparisons between the Pliocene control simulation and pre-industrial control, given that the Pliocene control simulation is run with PRISM4 boundary conditions that include significantly reduced ice sheet volume (specifically over West Antarctica and Greenland) as compared to the present-day. In general, it would be useful to see a more detailed discussion of how the sensitivity experiments presented here correspond to past/future scenarios that have been studied in the scientific literature.

Specific comments

Paragraph starting on line 50: You discuss using the mid-Pliocene warm period as an analog for end-of-century climate. The time-scales for changes in different parts of the Earth system differ; as you discuss, although present-day CO₂ concentrations are similar
to the Pliocene, it will take time for Earth’s global mean temperature to rise to Pliocene levels. It will also take time for vegetation to adjust to the Pliocene climate, and—importantly—for ice sheet loss comparable to Pliocene conditions to occur. I think this section needs to include some discussion of the existing scientific understanding of future changes in the volume of the East Antarctic Ice sheet, including the possible time-scales of ice sheet loss. How far into the future might we expect to see a mid-Pliocene-like East Antarctic Ice sheet volume?

Line 105, “our experiments focus on changing the East Antarctic Ice Sheet height”: this makes it sound like you are changing the East Antarctic Ice Sheet height against its modern or pre-industrial value, but you are changing the East Antarctic Ice Sheet height against its reconstructed Pliocene value.

Paragraph starting at line 108: I’d like to see more justification for this experimental design. Are the 0%EAIS, 25%EAIS, 50%EAIS, and 75%EAIS experiments intended to represent analogs for possible future scenarios, and if so under what conditions and over what time-scales could these scenarios arise?

Line 112: Are changes in the ice sheet dynamically resolved in the model, or are you manipulating the height of the ice sheet for each sensitivity simulation? This is unclear here.

Lines 112-118: Does the mid-Pliocene control experiment already have reduced EAIS volume, as specified in the PRISM4 boundary conditions? If so, it would be helpful to describe in more detail the differences between PRISM4 EAIS configuration and its present-day volume/extent.

Lines 188-191: The winds bringing moisture over the continent are different from the katabatic winds mentioned; it would be helpful to be more explicit here about the causal relationships between weakened katabatic flow and elevated moisture transport.

Lines 203-205: This is too vague.

Line 208: In section 4.4, you present a nice analysis of the energy balance, and find that “heat transport by winds from the Southern Ocean to Antarctica is the primary factor influencing the temperature changes over Antarctica.” Line 208 makes it sound like the atmospheric temperature lapse rate is the primary factor for warming over East Antarctica, which seems to contradict your findings in section 4.4.

Line 230: was EAIS height reduced below the PRISM4 reconstructed height during the mid-
Pliocene warm period? PRISM4 focused on a specific interglacial period, so the height of ice sheets would have fluctuated during the mid-Pliocene. But is there evidence to suggest that the EAIS would have disappeared completely? Or are these hypothetical scenarios? Again, the justification for the experimental design needs to be more clear.

Line 245: would this have effects on ocean gateways such as the Bering Strait, and what impact might this have on ocean dynamics? Would these effects be significant?

Section 4.4: Please add more detail about how you conducted this energy balance analysis.

Line 273: Which of these sensitivity experiments are applicable to which future and/or past climate scenarios? Please be more specific here.

Line 278: similar to previous comments—is there evidence for these changes in EAIS height actually occurring during the mid-Pliocene warm period? Or are these hypothetical scenarios?

**Technical corrections**

Line 59: would make more sense to write: “due to the large thermal inertia of the oceans, the global mean temperature is not projected to reach the level of the Pliocene until the 2040s.”

Line 85: this is the spatial resolution of, not over, the ocean—correct?

Line 194: Typo, MPComtrol to MPControl

Line 209: could change to “which can be explained by the lapse rate”

Line 219: rewrite as “leading to higher air pressure over Antarctica and lower air pressure over extra-Antarctic regions.”

Line 220: perhaps it would make more sense to replace “translate to” by “correspond
with.”

Line 232: “costal” to “coastal”

Line 269: there is no Section 4.4.4

Line 284-285: should be “the surface air temperature and the sea surface temperature both decrease…. The surface air pressure increases over East Antarctica, while decreasing elsewhere”

Line 286: awkward sentence. Could rewrite as: “Energy balance analyses show that the temperature changes over Antarctica are mainly caused by topographic changes in the EAIS.”
