Author comment on "A new estimate of oceanic CO\textsubscript{2} fluxes by machine learning reveals the impact of CO\textsubscript{2} trends in different methods" by Jiye Zeng et al., Earth Syst. Sci. Data Discuss., https://doi.org/10.5194/essd-2022-71-AC1, 2022

Thanks to the reader for the comment.

Strictly speaking, YEAR was not included in training machine learning models directly. Instead, the annual increase rates of CO\textsubscript{2} at decadal scales were extracted by an iteration method and the rates were used to remove the trend in CO\textsubscript{2} measurements. The trend removed (or normalized) data were used for training the models. The iteration method used machine learning to remove the dependence of CO\textsubscript{2} on SST, SSS, MDL, CHL, LAT and LON and used linear regression to remove the dependence of CO\textsubscript{2} on YEAR.

In addition to citing the reference of the iteration method, we will put the description in the next revision.
