On the lower limit of the linear recession constant
John Ding

Community comment on "Exploring the role of soil storage capacity for explaining deviations from the Budyko curve using a simple water balance model" by Jan Bondy et al., Hydrol. Earth Syst. Sci. Discuss., https://doi.org/10.5194/hess-2021-174-CC1, 2021

The linear recession constant \( k_{res} \) is one of four parameters in their Budyko framework. Lower and upper limits for parameter \( k_{res} \) are set by authors in Table 2 to be 0.05/d and 0.9/d, respectively.

Among 16 study catchments in Table C-1, three of whom reach the lower limit of 0.05/d: B-5, B-7 and P-1, but none the upper limit. (In Table C-1, \( K_{res} \) to read \( k_{res} \).

Since one or more of these three catchments may have a lower \( k_{res} \) value than 0.05/d, I suggest the lower limit be lowered by one order of magnitude to 0.005/d.
