Referee comment on "Assessing internal changes in the future structure of dry-hot compound events: the case of the Pyrenees" by Marc Lemus-Canovas and Joan Albert Lopez-Bustins, Nat. Hazards Earth Syst. Sci. Discuss.,
<https://doi.org/10.5194/nhess-2021-5-RC2>, 2021

General comments

Thank you for the opportunity to review the manuscript "Assessing internal changes in the future structure of Dry-Hot compound events. The case of the Pyrenees". The manuscript analyses a relevant topic and of wide interest in the scientific community related to compound events. In this work, the authors present a novel compound analysis of concurrent extreme dry spells and extreme hot temperature events in spring (MAM) and summer (JJA) on the Pyrenees, for the present and future scenarios. The proposed definition of the Dry-Hot events considers the length of extreme dry spells and the maximum and extreme maximum temperatures during the dry spells. The results point that present increases in compound Dry-Hot events are mainly attributed to increasing extreme temperatures, while future increases of the compound event will be likely associated to increases in both dry spells duration and extreme temperatures. Overall, the manuscript is well-conceived and organized, and the findings would be worth of publishing in NHESS. Nevertheless, I have some comments and suggestions detailed below that the authors may consider clarifying in the manuscript.

Specific comments

Introduction

- Line 29: The authors may consider to use 'compound manner' instead of 'composite

manner' to avoid confusion.

- Line 43: I recommend including a short introduction in one sentence to the definition proposed by Manning et al (2019) before this line.

Data and methods

- Line 76: I suggest the authors to provide some references about this: 'We focused on spring and summer, as spring can constitute the precursor of summer wildfires, and is a season prone to crop yield losses, etc.'
- Line 87: I suggest the authors to better explain why using the cell closest to the centroid of each region.
- Line 139-142:
 - I suggest the authors to better detail the estimation of the 90th percentile for D and EM events.
 - Could Figure 2 be illustrated with a particular observational year?
 - Would it be interesting to analyze the length of the EM events? (i.e. the number of consecutive extreme dry and hot days, in the addition of the value of $Tx > 90^{\text{th}}$ during D events)

Results

- Line 192: I suggest the authors to detail the calculation of the Tx anomalies, maybe in section 2.
- Line 199: I think the authors meant Figure 3, like in the parenthesis in the end of the sentence.
- Line 255: I suggest the authors to justify the use of a 7 year-moving average, maybe in section 2.
- Line 273-316:
 - I suggest the authors to describe in the section 2 the methods employed in the joint probability analysis of D and EM events.
 - The physical interpretation of the mean value of the bivariate distribution in Figure 10 is the likelihood of average D occurring given that average EM occurs?
 - Maybe Figure 11 could be moved to Supplementary.
- Line 283-284: "Nonetheless, in the case of summer for this same scenario, a small increase in the duration component was observed." I suggest adding to this sentence that the increase is higher from the first period to the second (2011-2040 to 2041-2070) than from the second to the third (2041-2070 to 2071-2100).
- Figure 10: Some information such as the regression line and the R-squared is not interpreted in the manuscript text.
- Line 301-316: I suggest specifying in parenthesis the Mediterranean and continental regions mentioned in the text, for example: Mediterranean regions (NMED and SMED).

Discussion

Line 327-329: 'A significant finding of our study indicates that there will be a significant increase in the future compound risk in relation both to the magnitude dimension (extreme temperature) and the duration dimension (duration of extreme dry event).' I suggest rephrasing indicating the regions, seasons and scenarios to which this finding applies.

Technical corrections

- In general, figure captions can be improved, e.g.:
 - Figure 4 – Indicate period as in Figure 3.
 - Figure 6 – Explain better the horizontal interval in D points.
 - Figure 10 – Explain the black dashed line, the black numbers over the isolines and the top equations.
 - Figure 11: Same as Figure 10, not 11.
- Line 80: AND in capital letters
- Section 5 title: 'future' to 'Future'
